YOUNG, EDWARD L., M.D.
YOUNG, ERNEST BOYEN, M.D.
YOUNG, JAMES HERBERT, M.D.

# INDEX TO VOLUME CLXIV.

## AUTHORS.

**Adams, John D.** The functional spine, 80.
**Alexander, G.** On the possible effect upon the auditory labyrinth of the Ehrlich-Hata remedy in the treatment of syphilis, 331.
**Alger, Ellice M.** Disturbances dependent on eyestrain, 142.
**Amoss, Harold L., Rosenau, M. J., and Sheppard, A. G.** Anterior poliomyelitis; attempts to transmit the disease to monkeys by inoculation with the nasal, pharyngeal and buccal secretions of eighteen human cases, 743.
**Arkin, Louis.** A new tonsil-seizing forceps, 571.
**Arms, B. L.** The public health laboratory, 817.
**Austin, A. E.** Alimentary gastric hypersecretion and gastric atony, 77; on the dependence of intestinal indigestion on gastric disturbances, 327; the classification of diabetes mellitus, 807.
**Ayer, S. H.** Medical inspection of schools in Boston, Mass., 456.

**Bailey, Pearce.** The aims and possibilities of neurological hospitals, 215.
**Barnes, Harry A.** Hemorrhage after tonsillectomy, 119.
**Barney, J. Dellinger.** The care and management of the tabetic bladder, 111. Prognosis and treatment, 13.
**Barney, J. Dellinger, and Young, Edward L.** The value of the guinea-pig test in genito-urinary tuberculosis, 917.
**Beebe, Theodore Chapin.** Liquid air in surgery, 384.
**Binney, Horace.** Present status of intravesical operations for tumors of the bladder, 226.
**Bond, Earl D.** Common salt and fluid retention. A clinical example, 85.
**Bowditch, Henry.** Infectious diarrhea. Its treatment with especial reference to the biochemical and bacteriological standpoint, 294.
**Bowen, Judson T.** Report on dermatology, 922.
**Bradford, E. H., Watson, F. S., and Monks, George H.** Herbert Leslie Burrell, M.D. (1856–1910.) In memoriam, 105.
**Brown, Lloyd T.** Pregnancy as a possible relief for visceral ptosis, 819.
**Bryant, W. Sohier.** Reflexes and reflex neuroses from the upper air tract (including the nose and pharynx), 144.
**Bullard, William N.** Mongolian idiocy, 56.
**Burrage, W. L.** Progress in gynecology, 338.

**Cabot, Arthur Tracy.** School inspection in small towns, 633.
**Cabot, Hugh.** The difficulties and limitations of diagnosis in advanced cases of renal tuberculosis, 634.
**Cabot, Richard C.** The Towns-Lambert treatment for morphinism and alcoholism, 676; on the relation between laboratory work and clinical work, 880.
**Chute, Arthur L.** An infection of the bladder with penicillium glaucum, 420.
**Clark, Payson J., and Richardson, Oscar.** Case of foreign body in the trachea, status lymphaticus. Death. Autopsy, 115.
**Codman, E. A.** Complete rupture of the supraspinatus tendon. Operative treatment with report of two successful cases, 708.
**Coffin, Rockwell A.** A case of pemphigus chronicus vulgaris of the oral cavity and larynx, 612.
**Coolidge, A., Jr.** Lateral deviations of the external nose, 850.
**Coues, Wm. Pearce.** A review of 214 cases of extra-uterine pregnancy at the Massachusetts General Hospital, Boston, 677; note on a case of paralysis agitans and cerebral arteriosclerosis, 754; some problems of school inspection, 814.
**Courtney, J. W.** The youthful psychopath, 219.
**Cowles, William N.** A case of diabetes treated by feeding of calves' pancreas, 921.
**Crockett, Eugene A.** When shall we remove tonsils and what type of opsration shall we do? 414.

**Davis, Lincoln.** Some clinico-pathological data on bladder tumors, 222; an analysis of forty-six cases of prostatectomy, 519, 565, 609, 630.
**Dearborn, George V. N.** The neurology of apraxia, 783.
**De Normandie, Robert L.** Report on obstetrics, 155.
**Drury, Dana W.** Double otitis media. Dehiscence of the floor of the cavum tympani. Streptococcus meningitis, 308.
**Dunn, Charles Hunter, and Rotch, Thomas Morgan.** Report on pediatrics, 17.

**Eaton, C. A., and Watters, W. H.** Vaccines in puerperal sepsis, 524.
**Ehrenfried, Albert.** Intrathoracic insufflation anesthesia: apparatus and cases, 532.
**Emmons, Arthur Brewster, 2d, and Huntington, James Lincoln.** A review of the midwife situation, 251.

**Farnell, Frederic J.** A case of progressive muscular atrophy, Charcot-Marie-Tooth type, 714.
**Faunce, Calvin B., Jr.** Acute toxemia caused by infection of the throat by the colon bacillus, 613.
**Fay, William E.** Looking backward, 287.
**Felsa, Henry O.** Recent experimental work on the "fusion" of nerves and its practical bearing on infantile paralysis. Report of a case of infantile paralysis treated by this method, 667.
**Fisher, Edward D.** What is the meaning of reflex? 149.
**Fox, Howard.** The action of salvarsan upon the Wassermann reaction, 776.
**Freedman, L. M.** The extirpation of the tonsil by enucleation: partly instrumental, partly by the use of the finger, 535.
**Frothingham, Channing, Jr.** Present treatment of gastric and duodenal ulcer. A review of the recent literature on the subject, 489.

**Giffin, H. Z.** The examination of the nose and throat in relation to general diagnosis. Results in asthma following nasal operation, 228.
**Goldthwait, Joel E.** The lumbo-sacral articulation. An explanation of many cases of "lumbago," "sciatica" and paraplegia, 365.
**Goodrich, Annie W.** The nurse and the public health, 443.
**Graves, W. P.** Diverticulitis of the sigmoid, 372.
**Gray, Elizabeth T.** Short résumé of the history of Cæsarean section, 884.
**Green, Charles M.** Five successive Cæsarean sections on the same woman, the fifth on twins. A unique obstetric history, 642.
**Green, Robert M.** Men, manners and medicine, 593.
**Green, Robert M., and Swift, John B.** Hemorrhagic disease of the newborn, 454.
**Greene, D. Crosby, Jr.** Report of three recent cases of bronchoscopy for foreign bodies, 117.

**Hall, G. W.** The treatment of gastric hyperacidity with hydrogen peroxide, 846.
**Hallock, Frank K.** The sanatorium treatment of neurasthenia and the need of a colony-sanatorium for the nervous poor, 73.
**Hanson, W. C., and Linenthal, H.** Progress in hygiene and state medicine, 648.
**Harrison, Paul W.** The intravenous use of cocaine. Report of a case, 151.
**Hartshorne, Isaac.** Accurate optics, 786.
**Hill, Eben C.** A simple, quickly removable head bandage, 460.
**Hill, T. Chittenden.** The treatment of fistula in ano, 334.
**Hinsdale, Guy.** Climatic treatment of tuberculosis, 596.
**Hobart, Mary Forrester.** Indications for Cæsarean section, 885.
**Holmes, Edgar M.** A case of vertigo cured by treatment of the Eustachian tube, 848.
**Hood, James A.** "Common colds," 604; the early diagnosis of pulmonary tuberculosis from the standpoint of physical and fluoroscopic examinations, 779.
**Huntington, James Lincoln, and Emmons, Arthur Brewster, 2d.** A review of the midwife situation, 251.

**Jones, Harold W.** Report of a series of cases of syphilis treated by Ehrlich's arsenobenzol at the Walter Reed General Hospital, District of Columbia, 381.

**Keefe, John W.** Some of the more important diseases of the upper abdomen that may require surgical intervention, 53.
**Kendall, Arthur I.** Bacillary dysentery. Its bacteriology, biochemistry and their relation to treatment, 288.
**Kendall, Arthur I., and Smith, Richard M.** Diarrhea in infants associated with the gas bacillus in the stools, 306.
**Kendall, Arthur I., and Walker, Arthur W.** The associated flora of bacillary dysentery, 301.
**Kerr, Isabelle D.** Plaster casting from life to show external deformities of the nose before and after correction, 831.
**Knapp, Philip Coombs.** The new neurological service at the Boston City Hospital; its first year's work, 218; the alleged increase of nervous diseases, 419; a case of hemiatrophy from scleroderma, 671.

**Ladd, W. E.** Treatment of intussusception in children, 712.
**Lane, John W.** Report of a case of full-term intra-abdominal pregnancy, 683.
**Lawrence, Charles H., Jr.** A method of collecting urine from female infants, 309.
**LeConte, Robert G.** Acute inflammation of long bones, with special reference to excision of the diaphysis, 771.
**Lee, Edward Wallace.** Acute dilatation of the stomach following surgical operations, 562.
**Leszynsky, William M.** Reflex symptoms and disease of the nervous system, 150.
**Linenthal, H., and Hanson, W. C.** Progress in hygiene and state medicine, 648.
**Lothrop, Oliver A.** A new tonsil knife, 153.
**Lovett, Robert W., and Sheppard, Philip A. E.** The occurrence of infantile paralysis in Massachusetts in 1910, 737.

**Mason, Nathaniel R.** Report of a case of the administration of one eighth of a grain of morphine to a baby two and one-half days old. Recovery, 190; the end results of Cæsarean section, 889.
**Mayo, William J.** Some observations on the disorders of the stomach and duodenum with especial reference to ulcers, 477.
**McCarthy, Francis P.** A review of sanitation in Panama, 49.
**McKeen, Sylvester F.** Sudden death following a prophylactic dose of diphtheria antitoxin. Autopsy reveals status lymphaticus, 503.
**Merrill, Wm. H.** A case of nerve deafness due to the toxemia of diabetes, 849.
**Monks, George H.** Some practical points in connection with dislocation of the hip, and its reduction by the method of Bigelow, 262.
**Monks, Geo. H., Bradford, E. H., and Watson, F. S.** Herbert Leslie Burrell, M.D. (1856–1910.) In memoriam, 105.
**Morris, Robert T.** Reflexes in surgical diagnosis, 141; acute postoperative dilatation of the stomach, 564.
**Morse, John Lovett.** Acute poliomyeloencephalitis (infantile paralysis), 41; address of the president before the New England pediatric Society, 414; meningitis in infancy, 701.
**Morse, John Lovett, and Talbot, F. B.** Report on pediatrics, 852.
**Murphy, Fred T.** Antiperistalsis in the intestine. A clinical observation, 154.

**Neff, Irwin H.** Institutional forms of manic-depressive insanity, 81; some of the medical problems of alcoholism, 112.

**Pate, John Randolph.** Reflex disturbances referable to the ear, 147.
**Pattrey, Francis W.** Progress in the theory and practice of medicine. New methods of demonstrating tubercle bacilli, 614.
**Paul, W. E.** The treatment of acute poliomyelitis, 46.
**Perkins, Jay.** The fresh-air school, 10.
**Perry, Arthur P.** Keratosis follicularis, 191.

**Quinby, William C.** A note on the symptomatology of abscess of the liver, 267.

**Reik, H. O.** Secondary efforts to hasten healing after mastoidectomy, 417.
**Reynolds, Edward.** Two cases of abdominal pregnancy, one at term, 681.
**Rhea, Lawrence J., and Young, Ernest Boyen.** Ovarian pregnancy. Report of a case, 264.
**Richardson, F. L.** Tendon suture, 752.
**Richardson, Mark Wyman, and Spooner, Lesley H.** Antityphoid inoculation as introduced into certain training schools for nurses in Massachusetts, 8.
**Richardson, Maurice H.** Remarks on a forbidding case of cancer permanently cured by radical excision, 920.
**Richardson, Oscar, and Clark, J. Payson.** Case of foreign body in the trachea. Status lymphaticus. Death. Autopsy, 115.
**Rogers, Mark H.** Prognosis and treatment of tuberculosis of the ankle in adults, 811.
**Rosenau, M. J., Sheppard, Philip A. E., and Amoss, Harold L.** Anterior poliomyelitis. Attempts to transmit the disease to monkeys by inoculation with the nasal, pharyngeal and buccal secretions of eighteen human cases, 743.
**Rotch, Thomas Morgan and Dunn, Charles Hunter.** Report on pediatrics, 17.
**Rushmore, Stephen.** Late Cæsarean section. Report of a case, 537.
**Russell, F. F.** The prevention and treatment of typhoid fever with antityphoid vaccine, 1.

**Scudder, Charles L.** The transperitoneal and suprapubic approach to tumors of the bladder, 224.
**Sever, James Warren.** Overgrowth of the epiphysis of the lower end of the femur with an obliteration of the epiphyseal line, 186; an experimental study of tendon regeneration, 748.
**Shattuck, F. C.** Hexamethylamine as a possible preventive of pneumococcus empyema, 842.
**Sheppard, Philip A. E., and Lovett, Robert W.** The occurrence of infantile paralysis in Massachusetts in 1910, 737.
**Sheppard, Philip A. E., Rosenau, M. J., and Amoss, Harold L.** Anterior poliomyelitis. Attempts to transmit the disease to monkeys by inoculation with the nasal, pharyngeal and buccal secretions of eighteen human cases, 743.
**Smith, G. G.** The surgical treatment of gonorrheal epididymitis, 151.
**Smith, Mary A.** Technic of the operation, 886.
**Smith, Richard M.** Silver nitrate irrigations in the treatment of infectious diarrhea in infants, 298.
**Smith, Richard M., and Kendall, Arthur I.** Diarrhea in infants associated with the gas bacillus in the stools, 306.
**Soutter, Robert.** Scoliosis with marked structural change and rotation, 557.
**Spooner, Lesley H., and Richardson, Mark Wyman.** Antityphoid inoculation as introduced into certain training schools for nurses in Massachusetts, 8.
**Stedman, Henry R.** Popular fallacies about insanity, 405.
**Sutton, Richard L.** Sporotrichosis in man and in the horse, 179; salvarsan ("606") in the treatment of chronic pemphigus, 336.
**Squier, J. Bentley.** Suprapubic intra-urethral enucleation of the prostrate, 911.

**Talbot, Fritz B.** Two methods of obtaining human milk for hospital use, 304.
**Talbot, Fritz B., and Morse, John Lovett.** Report on pediatrics, 852.
**Tenney, Benjamin.** The time and method for prostatectomy, 109.
**Towle, Harvey, P.** Progress in dermatology, 538, 571.
**Tuttle, James P.** Fibrous stricture of the rectum, 445.
**Tyrode, Maurice Vejux.** Indications from a medical standpoint for operative procedures in the presence of chronic gastric symptoms, 495; progress in pharmacology and experimental medicine, 684.

**Vietor, Agnes C.** The special relation of modern medicine to the health of women, 181.
**Vincent, Beth.** A case of intussusception, 309.

**Walker, Arthur W., and Kendall, Arthur L.** The associated flora of bacillary dysentery, 301.
**Walker, I. Chandler.** Tuberculous meningitis, with leucocytosis and a purulent exudation containing many bacilli. A case report, 816.
**Watson, F. S., Bradford, E. H., and Monks, George H.** Herbert Leslie Burrell, M.D. (1856–1910.) In memoriam, 105.
**Watters, W. H., and Eaton, C. A.** Vaccines in puerperal sepsis, 524.
**Wells, Orion V.** Hemorrhagic disease of the newborn; report of two cases in one family, 716.
**White, Charles J.** A summer service in the Weld Ward of the Massachusetts General Hospital, 643.
**White, Franklin W.** Duodenal ulcer, 482; further experience with the benzidin test for occult blood in diseases of the digestive organs, 876.
**Williams, John T.** Breast abscess during pregnancy with report of a case, 188; the immediate results of Cæsarean section, 888.
**Williams, John T., and Young, Ernest Boyen.** The results of the treatment of two thousand cases of miscarriage at the Boston City Hospital, 871.
**Wilson, W. E.** The disappearance of a catheter in the bladder and its subsequent spontaneous passage, 267.
**Worcester, A.** Obstetrics in general practice, 837.

**Yawger, N. S.** "Fibrositis" as a cause of chronic hypertrophic spondylitis and possibly with a heretofore undescribed sign in intestinal auto-intoxication, 843.
**Young, Edward L., and Barney, J. Dellinger.** The value of the guinea-pig test in genito-urinary tuberculosis, 917.
**Young, Ernest Boyen, and Rhea, Lawrence J.** Ovarian pregnancy. Report of a case, 264.
**Young, Ernest Boyen, and Williams, John T.** The results of the treatment of two thousand cases of miscarriage at the Boston City Hospital, 871.
**Young, James Herbert.** An analysis of one hundred and seventy-eight cases of infectious diarrhea in infants, 299; intussusception in children, 710.

## SUBJECTS.

**Abdomen**, upper, some of the more important diseases of, that may require surgical intervention, John W. Keefe, M.D., 53.
**Abscess**, breast, during pregnancy, John T. Williams, M.D., 188; liver, a note on the symptomatology of, William C. Quimby, M.D., 267.
**Acute Dilatation** of the stomach following surgical operations, Edward Wallace Lee, M.D., 562; of the stomach, Robert T. Morris, M.D., 564.
**Acute Poliomyelitis**, the treatment of, W. E. Paul, M.D., 46.
**Acute Poliomyeloencephalitis** (infantile paralysis), John Lovett Morse, A.M., M.D., 41.
**Addresses.** Address of the president before the New England Pediatric Society, John Lovett Morse, A.M., M.D., 414; men, manners and medicine, Robert M. Green, M.D., 593; the nurse and the public health, Annie W. Goodrich, R.N., 443.
**Alcoholism**, some of the medical problems of, Irwin H. Neff, M.D., 112; the Towns-Lambert treatment for morphinism and, Richard C. Cabot, M.D., 676.
**Alimentary Gastric Hypersecretion** and gastric atony, A. E. Austin, M.D., 77.
**Anesthesia**, intrathoracic insufflation: apparatus and cases, Albert Ehrenfried, M.D., 532.
**Anterior Poliomyelitis.** Attempts to transmit the disease to monkeys by inoculation with the nasal, pharyngeal and buccal secretions of eighteen human cases, M. J. Rosenau, M.D., Philip A. E. Sheppard, M.D., and Harold L. Amoss, M.D., 743.
**Antiperistalsis in the Intestine.** A clinical observation, Fred T. Murphy, M.D., 154.
**Antityphoid Inoculation** as introduced into certain training schools for nurses in Massachusetts, Mark Wyman Richardson, M.D., and Lesley H. Spooner, M.D., 8.
**Antityphoid Vaccine**, the prevention and treatment of typhoid fever with, F. F. Russell, M.D., 1.
**Apraxia**, the neurology of, George V. N. Dearborn, M.D., 783.
**Arteriosclerosis**, cerebral, and paralysis agitans. Note on a case of, Wm. Pearce Coues, M.D., 754.
**Asthma**, results in, following nasal operation, H. Z. Giffin, M.D., 228.
**Atrophy**, a case of progressive muscular, Charcot-Marie-Tooth type, Frederic J. Farnell, M.D., 714.
**Auditory Labyrinth**, on the possible effect upon, of the Ehrlich-Hata remedy in the treatment of syphilis, Prof. G. Alexander, M.D., 331.

**Bacillary Dysentery.** See "Dysentery."
**Bandage**, head, Eben C. Hill, M.D., 460.
**Bladder**, an infection of the, with penicillium glaucum, Arthur L. Chute, M.D., 420; the disappearance of a catheterin in, W. E. Wilson, M.D., 267.
**Bladder Tumors**, present status of intravesical operations for, Horace Binney, M.D., 226; some clinico-pathological data on, Lincoln Davis, M.D., 222; the transperitoneal and suprapubic approach to, Charles C. Scudder, M.D., 224.
**Bones**, long, acute inflammation of, with special reference to excision of the diaphysis, Robert G. Le Conte, M.D., 771; the lumbo-sacral articulation. An explanation of many cases of "lumbago," "sciatica" and parapiegia, Joel E. Goldthwait, M.D., 365; overgrowth of the epiphysis of the lower end of the femur, James Warren Sever, M.D., 186; tuberculosis of the ankle in adults, prognosis and treatment of, Mark H. Rogers, M.D., 811.
**Book Reviews.** Ellice M. Alger, refraction and motility of the eye, 424; Mrs. Martha M. Allen, alcohol: a dangerous and unnecessary medicine, 125; annual report of the Surgeon-General of the Public Health and Marine-Hospital Service of the United States. For the fiscal year 1909, 463; Edwin Ash, mind and health, 199; James Moores Ball, Andreas Vesalius, the reformer of anatomy, 426; S. Wyllis Bandler, vaginal celiotomy, 426; W. Blair Bell, the principles of gynecology, 273; D. H. Bergey, the principles of hygiene, 425; Sherman G. Bonney, pulmonary tuberculosis and its complications, 793; Louie Croft Boyd, state registration for nurses, 896; J. Milne Bramwell, hypnotism and treatment by suggestion, 125; Albert H. Brundage, a manual of toxicology, 425; Henry A. Cables, golden rules of diagnosis and treatment of diseases, 426; William Francis Campbell, a textbook of surgical anatomy, 855; Ludovico Cecchini, sanitary statistics of the Italian navy for the years 1905–1906, 274; the proceedings of the Charaka Club, Volume III, 723; Committee on Nurses of the Manhattan Eye, Ear, Nose and Throat Hospital, nursing in diseases of the eye, ear, nose and throat, 26; Harry Sturgeon Crosers, diagnosis and treatment of diseases of women, 273; T. D. Crothers, inebriety, 426; Arthur R. Cushny, a textbook of pharmacology and therapeutics, or the action of drugs in health and disease, 165; George V. N. Dearborn, moto-sensory development, 856; Pierre Descompa, the coeliac axis, 688; Margaret Frances Donahoe, a manual of nursing, 166; Alvah H. H. Doty, prevention of infectious diseases, 856; Seneca Egbert, a manual of hygiene and sanitation, 856; P. Ehrlich and A. Lazarus, anemia. Part I, Vol. I, 688; epidemic poliomyelitis. Report of the collective investigation Committee on the New York epidemic of 1907, 92; Francis Ashley Faught, essentials of laboratory diagnosis, 758; Johann Fein, hints for the general practitioner in rhinology and laryngology, 426; W. Soltau Fenwick, dyspepsia. Its varieties and treatment, 758; A. Dingwall Fordyce, the hygiene of infancy and childhood and the underlying factors of disease, 166; J. M. Fortescue-Brickdale, a practical guide to the newer remedies, 823; W. E. Fothergill, manual of diseases of women, 856; Anna M. Galbraith, personal hygiene and physical training for women, 823; E. Baldwin Gleason, a manual of diseases of the nose, throat and ear, 723; David Allyn Gorton, the history of medicine, philosophical and critical, from its origin to the twentieth century, 856; Alfred Pearce Gould, the Bradshaw lecture on cancer, 463; C. E. Green, the cancer problem, 723; David Berry Hart, phases of evolution and heredity, 199; Henri Hartmann, gynécologie opératoire, 724; George Herschell, the non-surgical treatment of duodenal ulcer, 165; Philip Hanson Hiss and Hans Zinsser, a textbook of bacteriology, 166; Julius Hoffman, Ludwig Pöhlman, and John George Garson, remedial gymnastics for heart affections,—a translation of "Die Gymnastik der Herzleidenden," 823; Henry Jellett, a manual of midwifery, 165; Edwin L. Jordan, a textbook of general bacteriology, 165; A. O. J. Kelly, the practice of medicine, 62; LeGrand Kerr, the care and training of children, 723; A. F. A. King, a manual of obstetrics, 165; Arnold C. Klebs, tuberculosis, 652; Felix Lejars, urgent surgery. Vol. II, 300; H. Edwin Lewis, pneumonia, 62; H. W. Longyear, nephrocoloptosis, 275; A. Manquat, principles of therapeutics, 199; A. Marie, pellagra, 274; Francis H. A. Marshall, the physiology of reproduction, 723; W. H. Martindale and W. W. Westcott, extra pharmacopeia, 275; W. Harrison Martindale, organic analysis chart, 578; C. A. McBride, the modern treatment of alcoholism and drug narcotism, 346; Robert S. McCoombs, diseases of children for nurses, 463; Joseph McFarland, a textbook of pathology, 578; Joseph McFarland, a textbook upon the pathogenic bacteria, for students of medicine and physicians, 578; Joseph McFarland, biology, general and medical, 793; J. Ewing Mears, the problem of race betterment, 578; Rutherford Morison, an introduction to surgery, 823; John Lovett Morse, case histories in pediatrics, 545; James Gregory Mumford, the practice of surgery, 198; John H. Musser and A. O. J. Kelly, a handbook of practical treatment, Volumes I and II, 824; C. Muthu, pulmonary tuberculosis and sanatorium treatment, 824; Burt E. Nelson, introduction to the analysis of drugs and medicines, 688; Heinrich Neumann, otitic cerebellar abscess, 239; Isaac Ott, internal secretions from a physiological and therapeutic standpoint, 723; M. G. Overlock, the working people; their health and how to protect it, 239; Alida Frances Pattee, practical dietetics, with reference to diet in disease, 307; Archibald Stanley Percival, the prescribing of spectacles, 307; L. Bathe Rawling, landmarks and surface markings of the human body, 794; report of the (New South Wales) Government Bureau of Microbiology; Sydney, 166; report of the Commissioner of Education for the year ended June 30, 1910. Vol. I, 198; John W. Ritchie and Joseph S. Caldwell, primer of hygiene, 652; Albert Robin, common practical therapeutics, 724; E. A. Schäfer, the essentials of histology, descriptive and practical, for the use of students, 345; G. E. de Schweinitz, diseases of the eye, a handbook of ophthalmic practice, 274; state board examination questions and answers of forty-one states and two Canadian provinces, 92; A. A. Stevens, modern materia medica and therapeutics, 274; Julia C. Stimson, nurses' handbook of drugs and solutions, 617; Emily M. A. Stoney, bacteriology and surgical technic for nurses, 166; Sinclair Tousey, medical electricity and Röntgen rays, 345; Samuel E. Tracy, studies in invalid occupation, 345; transactions of the Fourth International Sanitary Conference of the American republics, 507; Henry Enos Tuley, obstetrical nursing for nurses and students, 314; Dawson Turner, radium, 723; Thomas D. Tuttle, principles of public health, 652; Victor G. Vecki, the prevention of sexual diseases, 617; Ralph Vincent, on acute intestinal toxemia in infants, 617; Albert J. Walton, fractures and separated epiphyses, 346; George Lincoln Walton, those nerves, 346; John E. Weeks, a treatise on diseases of the eye, 687; William Wellington, movable kidney, 92; Charles J. Whitby, makers of man, 687; Royal Whitman, a treatise on orthopedic surgery, 274; DeForest Willard, the surgery of childhood, 688; Philip Zenner, education in sexual physiology and hygiene, 652; Annual Report of the Surgeon General of the Public Health and Marine Hospital Service of the United States for the year 1910, 932; Emil G. Beck, Bismuth Paste in Chronic Suppurations, 932.
**Boston City Hospital**, the new neurological service at, its first year's work, Philip Coombs Knapp, A.M., M.D., 218.
**Breast Abscess** during pregnancy, with report of a case, John T. Williams, M.D., 188.
**Bronchoscopy for Foreign Bodies**, report of three recent cases of, D. Crosby Greene, Jr., M.D., 117.
**Burrell**, Herbert Leslie, M.D. (1856–1910.) In memoriam. Tributes from Drs. E. H. Bradford, F. S. Watson and George H. Monks, 105.

**Cæsarean Section**, the end results of, Nathaniel R. Mason, M.D., 889; short résumé of the history of, Elizabeth T. Gray, M.D., 884; the immediate results of, John T. Williams, M.D., 888; indications for, Mary Forrester Hobart, M.D., 885; five successive, on the same woman, the fifth on twins. A unique obstetric history, Charles M. Green, M.D., 642; late. Report of a case, Stephen Rushmore, M.D., 537; technic of the operation, Mary A. Smith, M.D., 886.
**Cancer**, remarks on a forbidding case of, permanently cured by radical excision, Maurice H. Richardson, M.D., 920.
**Chronic Gastric Symptoms**, indications from a medical standpoint for operative procedures in the presence of, Maurice Vejux Tyrode, M.D., 905.
**Clinical Work** and laboratory work, on the relation between, Richard C. Cabot, M.D., 880.
**Cocaine**, the intravenous use of. Report of a case, Paul W. Harrison, M.D., 151.
**Colony Sanatorium** for the nervous poor, Frank K. Hallock, M.D., 73.
**"Common Colds,"** James A. Honeij, M.D., 604.
**Correspondence.** Elevators at elevated and subway stations, Edward M. Buckingham, 177; sex and education, Richard C. Cabot, 104; lectures of former professors of theory and practice of physic at Harvard, Henry A. Christian, 178; "proposed homeopathic sanatoria for consumptives," Herbert C. Clapp, 325; an anecdote about Cheselden, Charles G. Cumston, 326; Charles II—a therapeutic nihilist, Charles G. Cumston, 177; bleeding "gratis," Charles G. Cumston, 593; use of the incubator in study of embryology, Charles G. Cumston, 806; organic arsenic preparations and "606," Spencer L. Dawes, 39; letter from the Philippines. Changes in medical officers. Taal volcano eruption. Annual meeting of the Medical Association. Polished rice and beriberi. Salvarsan in syphilis and yaws. Ultraviolet rays. Amebic dysentery. General health con-

ditions, "G." 591; a letter from Bermuda, George W. Gay, 492; the best route to see the wonders of the western slope, George W. Gay, 555; "a possible cure for cancer." A correction, Harvey R. Gaylord, 214; treatment of phthisis by antiseptic inhalation, John B. Hawes, 2d, 286; relative to climate in hay fever, F. W. Hornbrook, 404; Professor Fisher's report on national vitality, Lawrence Irwell, 556; the American Association in Los Angeles, Walter Lindley, 665; a centenarian, Charles E. Morse, 104; antiseptic inhalations in pulmonary tuberculosis, Beverley Robinson, 364; the medical profession must change its tactics, William J. Robinson, 71; Paris letter. The latest treatment for tuberculosis. Declining birth-rate in France, "S.," 176; Paris letter. A few notes on altitude climates, "S.," 362; Paris letter. Tincture of iodine as a surgical antiseptic, "S.," 630; the heredity of insanity, E. E. Southard, 72; application of iodine to tonsils, Edmund D. Spear, 700; the best route to see the wonders of the western slope, George S. Whiteside, 665; tincture of iodine as an antiseptic, Frank Thomas Woodbury, 735.

**Deafness**, a case of nerve, due to the toxemia of diabetes, Wm. H. Merrill, M.D., 849.

**Dermatology**, progress in, Harvey P. Towle, M.D., 538, 571; summer service in the Weld ward of the Massachusetts General Hospital, Charles J. White, M.D., 643; progress in, John T. Bowen, M.D., 922.

**Deviations**, lateral, of the external nose, A. Coolidge, Jr., M.D., 850.

**Diabetes**, a case of, treated by feeding of calves' pancreas, William N. Cowles, M.D., 921.

**Diabetes Mellitus**, the classification of, A. E. Austin, M.D., 807; nerve deafness due to, Wm. H. Merrill, M.D., 849.

**Diaphysis**, excision of, acute inflammation of long bones with especial reference to, Robert G. LeConte, M.D., 771.

**Diarrhea, infectious.** Its treatment with especial reference to the biochemical and bacteriological standpoint, Henry I. Bowditch, M.D., 724; silver nitrate irrigations in the treatment of, in infants, Richard M. Smith, M.D., 298; an analysis of one hundred and seventy-eight cases of, in infants, James Herbert Young, M.D., 299; in infants associated with the gas bacillus in the stools, Arthur I. Kendall, Ph.D., and Richard M. Smith, M.D., 306.

**Digestive Organs.** Further experience with the benzidin test for occult blood in diseases of the, Franklin W. White, M.D., 876.

**Diphtheria Antitoxin**, sudden death following a prophylactic dose of. Autopsy reveals status lymphaticus, Sylvester F. McKeen, M.D., 503.

**Dislocation of the Hip** and its reduction by the method of Bigelow. Some practical points in connection with, George H. Monks, M.D., 262.

**Diverticulitis** of the sigmoid, W. P. Graves, M.D., 372.

**Duodenal Ulcer**, Franklin W. White, M.D., 482; some observations on the disorders of the stomach and duodenum with especial reference to ulcers, William J. Mayo, M.D., 477; present treatment of gastric and. A review of the recent literature on the subject, Channing Frothingham, Jr., M.D., 480.

**Dysentery**, bacillary. Its bacteriology, biochemistry and their relation to treatment, Arthur I. Kendall, 388; the associated flora of, Arthur I. Kendall, M.D., and Arthur W. Walker, M.D., 301.

**Editorials.** Medical and human progress, 27; the case of antityphoid inoculation, 28; eugenics and divorce, 28; liability of municipalities for water pollution, 29; responsibility of physicians for vital statistics, 29; the vanishing birth-rate of civilization, 62; death-rates in Boston and elsewhere, 63; termination of the typhoid epidemic at Annapolis, 63; some large bequests in medical charity, 63; ideals in sex education, 93; the migration of hospitals, 94; proposed milk legislation in Massachusetts, 94; municipal hospital in Cambridge, 95; projected endowment for Harvard Dental school, 95; recent progress in syphilis, 126; college women as mothers, 127; decrease of smallpox as an index of enlightenment, 127; Sir Francis Galton, 128; Inaccuracy of vital statistics in the United States, 129; protection of infants and children, 167; life insurance and preventive medicine, 168; report and recommendations of the Massachusetts Milk Committee, 169; the future of human lactation, 169; isolation of diphtheria carriers in Chicago, 169; the dust nuisance in the street and the hygienic legislative measures to be taken in Massachusetts, 199; the prevention of blindness from ophthalmia neonatorum, 200; the resignation of Dr. Owen Copp, 201; centralization and decentralization of population, 202; the optometry bill again, 202; prosecutions under the Pure Food Law in Massachusetts, 203; factory and school hygiene, 240; proposed sanatoria for consumptives, 241; international congress on hygiene and demography, 242; preparation of antimeningitis serum, 242; large and small families, 242; the economic argument in preventive medicine, 275; the case of the midwife, 276; determination and numerical relation of sex, 276; the death-rate of London, 277; optometry, 277; noting the "imperceptible," 313; proposed homeopathic sanatoria for consumptives, 316; report of the Rhode Island Tuberculosis Commission, 316; a new bacteriologic museum, 317; potential longevity in man and other animals, 317; insanity in London, 318; report of the Commission on Factory Inspection, 347; philanthropy, medicine and the limitation of families, 349; the growth of American universities, 349; annual report of the Carnegie Foundation, 350; four recent hospital reports, 350; the work of the Floating Hospital, 351; report of the Massachusetts State Board of Health for 1909, 391; the status of antivivisection, 391; poliomyelitis in the United States in 1910, 392; Dr. Irving Fisher's report on national vitality, 393; ancient and modern food adulteration, 393; Dr. Johnson and the medical profession, 427; recommendations for the prevention of degeneracy, 427; smallpox and vaccination in the Philippines, 428; doctors and barbers, 429; an obstetric anomaly, 430; Garth, Dryden and "The Dispensary," 464; Bernard Shaw and the doctors, 464; legal status of the Blazek twins, 465; the question of dual personalities, 466; proposed subsidy for childbearing in Illinois, 467; oriental and occidental rates of increase in population, 467; limitation of the undesirable, 508; some proposed Illinois legislation, 508; the prevention of violent death from fire, 509; Asklepios and the goose, 510; a notable memorial meeting, 510; inspection of tenement house work-rooms, 546; Claude Martin and autolithotrity, 546; the diptank decision, 547; work of the Philippine Health Bureau, 547; efficiency of work on Monday, 548; restraint of the insane, 579; Thucydides and the Athenian epidemic of plague, 580; science and method, 580; International Congress on Hygiene and Demography, 581; distribution of spotted fever tick, 581; [illegible]neric physicians, 618; the New York Neurological Institute, 619; [illegible] Metropolitan Water and Sewerage Board, 620; Arthurian physi[illegible]s, 654; the moral of the three-legged chicken, 655; smallpox and vac[illegible]nation in Cuba, 656; the plague in Asia, 656; Dresden International Hygiene Exposition, 689; an uncrowned king, 689; a new pregnancy clinic, 690; compensation for industrial accidents, 690; report of Boston State Hospital, 690; increase of suicide in the United States, 691; the passing of a medical landmark, 724; nature and eugenics, 725; the annual meeting of The Massachusetts Medical Society, 726; expedition to study mountain sickness, 727; work of the Army Medical Corps in the eradication of smallpox, 727; the origin of the office of coroner, 759; Lucretius and the plague, 759; plot to assassinate prison officials, 760; the water-supply of Boston, 760; Harvard school for advanced instruction in medicine, 761; a hospital for private patients, 761; some modern aspects of English race migration, 794; the main gateway to the western world, 795; meeting for the Boston Infants' Hospital, 796; use of saccharine in foodstuffs, 797; restoration of the army canteen, 825; problems of the milk supply, 826; hours of work for nurses, 826; Pure Food Law covers the ingredients, not the virtue of contents, 827; Sir James Young Simpson, 857; some possibly fruitless modes of social endeavor, 858; sanitary conditions of Massachusetts foundries, 859; the new medical building of McGill University, 859; centennial of the Rhode Island Medical Society, 860; testimonial to Dr. Owen Copp, 860; annual meeting of The Massachusetts Medical Society, 897; the Wesson Maternity Hospital, 898; the celebration and sequelæ of patriotic holidays, 899; genius, eugenics, and degeneracy, 899; a British compliment to Boston, 900; proposed amendment of Pure Food and Drug Law, 933; care and prevention of blindness, 934; opening of the Floating Hospital season, 934; experimental measles in the monkey, 935.

**Empyema** pneumococcus, hexamethylamine as a possible preventive of, F. C. Shattuck, M.D., 842.

**Epiphysis**, overgrowth of, of the lower end of the femur with an obliteration of the epiphyseal line, James Warren Sever, M.D., 186.

**Eyestrain**, disturbances dependent on, Ellice M. Alger, M.D., 142.

**Examination** of the nose and throat in relation to general diagnosis. Results in asthma following nasal operation, H. Z. Giffin, M.D., 228.

**"Fibrositis"** as a cause of chronic hypertrophic spondylitis and possibly with a heretofore undescribed sign in intestinal auto-intoxication, N. S. Yarger, M.D., 843.

**Fibrous Strictures** of the rectum, James P. Tuttle, M.D., 445.

**Fistula in Ano**, the treatment of, T. Chittenden Hill, M.D., 334.

**Fluid Retention**, common salt and, Earl D. Bond, M.D., 85.

**Follicularis Keratosis**, Arthur P. Perry, M.D., 191.

**Gastric Disturbances**, the dependence of intestinal indigestion on, A. E. Austin, M.D., 327.

**Gastric Hyperacidity**, the treatment of, with hydrogen peroxide, G. W. Hall, M.D., 846.

**Gastric Hypersecretion and gastric ulcer**, A. E. Austin, M.D., 77.

**Gastric Symptoms**, chronic, Maurice Vejux Tyrode, M.D., 495.

**Genito-Urinary.** The disappearance of a catheter in the bladder and its subsequent spontaneous passage, W. E. Wilson, M.D., 267; the time and method for prostatectomy, Benjamin Tenney, M.D., 109; an analysis of forty-six cases of prostatectomy, Lincoln Davis, M.D., 519, 565, 609, 639; the difficulties and limitations of diagnosis in advanced cases of renal tuberculosis, Hugh Cabot, M.D., 634; suprapubic intra-urethral enucleation of the prostrate, J. Bentley Squier, M.D., 911; the value of the guinea-pig test in genito-urinary tuberculosis, J. Dellinger Barney, M.D., and Edward L. Young, M.D., 917.

**Guinea-Pig Test**, the value of, in genito-urinary tuberculosis, J. Dellinger Barney, M.D., and Edward L. Young, M.D., 917.

**Gonorrheal Epididymitis**, the surgical treatment of, G. G. Smith, M.D., 151.

**Gynecology**, report on, Walter L. Burrage, M.D., 338; the special relation of modern medicine to the health of women, Agnes C. Vietor, M.D., 181; ovarian pregnancy, report of a case, Ernest Boyen Young, M.D., and Lawrence J. Rhea, M.D., 264; report of a case of full-term intra-abdominal pregnancy, John W. Lane, M.D., 683; two cases of abdominal pregnancy, one at term, Edward Reynolds, M.D., 681; a review of 214 cases of extra-uterine pregnancy at the Massachusetts General Hospital, Wm. Pearce Coues, M.D., 677.

**Head Bandage**, Eben C. Hall, M.D., 360.

**Hemiatrophy from Scleroderma**, a case of, Philip Coombs Knapp, A.M., M.D., 671.

**Hemorrhagic** disease of the newborn, Robert M. Green, M.D., and John B. Swift, Jr., M.D., 454; report of two cases in one family, Orion T. Wells, M.D., 716.

**Hexamethylamina** as a possible preventive of pneumococcus empyema, F. C. Shattuck, M.D., 842.

**Hygiene** and state medicine, progress in, Wm. C. Hanson, M.D., and H. Linenthal, M.D., 648.

**Idiocy**, Mongolian, William N. Bullard, M.D., 56.

**Indigestion**, intestinal, on gastric disturbances, the dependence of, A. E. Austin, M.D., 327.

**Infantile Paralysis**, John Lovett Morse, A.M., M.D., 41; recent experimental work on the "fusion" of nerves and its practical bearing on, report of a case of infantile paralysis treated by this method, Henry O. Feiss, M.D., 667; the occurrence of, in Massachusetts in 1910. Reported for the Massachusetts State Board of Health, Robert W. Lovett, M.D., and Philip A. E. Sheppard, M.D., 737. See also Poliomyelitis.

**Inflammation**, acute, of long bones, with special reference to excision of the diaphysis, Robert G. LeConte, M.D., 771.

**Inoculation**, antityphoid, in certain training schools, Mark Wyman Richardson, M.D., and Lesley H. Spooner, M.D., 8; antityphoid, F. F. Russell, M.D., 1.

**Insanity**, popular fallacies about, Henry R. Stedman, M.D., 405; institutional forms of manic-depressive, Irwin H. Neff, M.D., 81.

**Institutional Forms** of manic-depressive insanity, Irwin H. Neff, M.D., 81.

**Instruments**, new. See New Instruments.

**Intestine**, antiperistalsis in, Fred T. Murphy, M.D., 134.

**Intestinal Disturbances** in infants: symposium, 287.

**Intestinal indigestion** ... gastric disturbances, the dependence of, A. E. Austin, M.D.

**Intrathoracic Insufflation Anesthesia**, Albert Ehrenfried, M.D., 532.

**Intussusception**, in children, James Herbert Young, M.D., 710, treatment of, W. E. Ladd, M.D., 712; a case of, Beth Vincent, M.D., 309.

**Keratosis Follicularis**, Arthur P. Perry, M.D., 191.

**Laboratory Work** and clinical work, on the relation between, Richard C. Cabot, M.D., 880.

**Laryngology.** Toxemia caused by infection of the throat by the colon bacillus, Calvin B. Faunce, Jr., M.D., 613; bronchoscopy for foreign bodies, D. Crosby Greene, Jr., M.D., 117; a case of pemphigus chronicus vulgaris of the oral cavity and larynx, Rockwell A. Coffin, M.D., 612; the examination of the nose and throat in relation to general diagnosis. Results in asthma following nasal operation, H. Z. Giffin, M.D., 228. See Tonsils.

**Liquid Air** in surgery, Theodore Chapin Beebe, M.D., 384.

**Liver**, a note on the symptomatology of abscess of, William C. Quinby, M.D., 267.

**Looking Backward**, William E. Fay, M.D., 287.

**Lumbo-Sacral** articulation. An explanation of many cases of "lumbago," "sciatica" and paraplegia, Joel E. Goldthwait, M.D., 365.

**Manic-Depressive Insanity**, institutional forms of, Irwin H. Neff, M.D. 81.

**Mastoidectomy**, secondary efforts to hasten healing after, H. O. Reik, M.D., 417.

**Medicine**, progress in the theory and practice of. New methods of demonstrating tubercle bacilli, Francis W. Palfrey, M.D., 614; modern, the special relation of, to the health of women, Agnes C. Vietor, M.D., 181.

**Medical Progress.** Report on gynecology, Walter L. Burrage, 338; report on obstetrics, Robert L. DeNormandie, 155; progress in hygiene and state medicine, Wm. C. Hanson and H. Linenthal, 648; progress in the theory and practice of medicine. New methods of demonstarting tubercle bacilli, Francis W. Palfrey, 614; report on pediatrics. Thomas Morgan Rotch and Charles Hunter Dunn, 17; progress in dermatology, Harvey P. Towle, 531; 571; progress in pharmacology and experimental therapeutics, Maurice Vejux Tyrode, 684; report on dermatology, John T. Bowen, 922.

**Men, Manners and Medicine**, Robert M. Green, M.D., 503.

**Meningitis in Infancy**, John Lovett Morse, A.M., M.D., 701; tuberculous, with leucocytosis and a purulent exudation containing many bacilli. A case report, I. Chandler Walker, M.D., 816.

**Midwife Situation**, a review of the, Arthur Brewster Emmons, 2d, M.D., and James Lincoln Huntington, M.D., 251.

**Milk**, human, two methods of obtaining, for hospital use, Fritz B. Talbot, M.D., 304.

**Miscarriage**, the results of the treatment of two thousand cases of, at the Boston City Hospital, Ernest Boyen Young, M.D., and John T. Williams, M.D., 871.

**Miscellany.** A discussion of leprosy, 38; Massachusetts Board of Registration in Medicine, 39; seizures of impure foods, 39; variations of annual precipitation in Boston, 39; medical inspection of factories, 70; Boylston Medical Society, 1811–1911, 71; medical policy of the Boston Milk and Baby Hygiene Association, 137; New York Academy of Medicine. Edward N. Gibbs memorial prize, 138; an auto-aseptic thermometer case, 139; medical matters in the Philippines, 139; leprosy, beri-beri, yaws and "606," 139; expenditures for conservation of health, 140; The Massachusetts Medical Society, 211; industrial treatment of the insane at the Gardner state colony, 213; centenarians in England, 213; treatment of phthisis by antiseptic inhalation, 213; progress of the plague in China, 250; instruction of hospital corps in the navy, 285; continuance of the plague in Asia, 285; Massachusetts tuberculosis conference, 325; Massachusetts Medical Society. Annual meeting, 1911. Preliminary announcement of the Committee of Arrangements, 361; a lay estimate of the doctor, 361; report of the committee of the American Neurological Association appointed to inquire into the occurrence of mental disease among persons employed by transportation companies, made to the association at the meeting in Washington, May, 1910, 401; education in "sex hygiene," 401; physicians as prison wardens, 402; medical inspection of schools in Minneapolis, 441; resolutions on the death of Dr. James H. Penny, 442; the Panama canal and tick-infected areas, 475; fatalities from plague in the Orient, 476; the cholera epidemic at Madeira, 517; distribution of Irish-born population, 517; work of the Rockefeller Hookworm Commission, 518; health inspection in factories, 555; diffusion of uniform public health methods, 590; American Physical Education Association, 590; interpretation of Pure Drug Law, 590; the Strassburg municipal dental clinic, 590; bubonic plague in the Orient, 591; in memory of John C. Munro, M.D., 591; effect of choline derivatives on blood-pressure, 591; unfortunate connotation of "606," 591; medicine as a "light business," 591; in memory of Henry P. Bowditch, M.D., 629; the use of condensed milk, 630; sanitary conditions in Panama, 663; resolutions against consolidation of Massachusetts registration boards, 663; the Marie Feodorovna Red Cross prizes, 664; International Sanitation Congress in Paris, 664; Oliver Cromwell's head, 664; eradication of plague in California, 664; eugenics: meeting of section of American Breeders' Association, 699; in memoriam: Dr. Percy D. # THE PREVENTION AND TREATMENT OF TYPHOID FEVER WITH ANTITYPHOID VACCINE.*

BY F. F. RUSSELL, M.D., WASHINGTON, D. C.,
*Major Medical Corps, U. S. Army.*

To the student of medicine not engaged in the treatment of individual cases of illness the great field of preventive medicine offers many attractive subjects, and in planning the prevention of disease nothing appeals to the sanitarian, or even the public at large, as does the conquest of typhoid fever.

We have some notable instances in other diseases, as in Malta fever, of the effect of preventive measures. This disease formerly necessitated the invaliding of many men of the English navy from the Mediterranean to home stations. The milk of goats having been proved through laboratory investigations to contain the *causus morbi*, the use of such milk was discontinued and the disease immediately ceased to exist in the navy. Malaria and yellow fever also promptly disappear following the application of proper prophylactic measures. In these three disorders the disease is shared in common by man and an alternative host; under such conditions, or whenever the responsibility for the survival of the disease be divided, the application of preventive measures is apt to be crowned with success. On the other hand, in diseases confined exclusively to human beings, as typhoid and pulmonary tuberculosis, the problem of prevention is much more difficult. Here the chronic carrier of the infection is a human being possessing almost equal rights with the healthy; he cannot be exterminated nor even confined to certain precincts, consequently more intricate and detailed measures must be found to prevent the passage of the infecting agent from the carrier to the well.

Typhoid spreads through such various channels that the problem of prevention has been attacked in as many ways, each of which may be suitable under given conditions. Epidemiological studies have shown a distinct difference between the course of typhoid in rural and urban populations. In cities the introduction of adequate sewerage systems, together with pure water and improved milk supplies, is usually followed by a reduction in the typhoid rate; where this can be done the disease ceases to be one of the greater problems. But in rural districts, on the other hand, there is little or no change from year to year in the methods used for the disposal of human wastes, the protection and purification of water supplies or in the control of infectious diseases; we find that year in and year out the typhoid rate remains high in rural communities.

In the military service we are confronted with both these conditions; our garrisoned posts correspond to cities, while maneuver and mobilization camps represent the country districts. The typhoid rate among troops in garrison has fallen year by year until it is now but about one half that of the civil population of military age. Were our troops always in garrison, the usual sanitary measures might afford adequate protection, but in camps, on marches and in actual warfare the conditions are radically changed. In the United States we have no permanent camp sites provided with sewer and water systems, each camp from a sanitary point of view being but a raw and crude rural community, liable to all the sanitary ills of such social units; worse even than the average village in some ways, since it is established in a hurry with no thought of permanency, on lines dictated by reasons of strategy rather than those of convenience or health. The entire population is housed under canvas; and tents being heavy and bulky, only the number necessity demands are carried on the wagon trains. This produces some overcrowding and a degree of personal contact between men which rarely exists in civil life outside of railroad and mining camps. The conditions are consequently most favorable for the introduction and spread of any infectious disease existing among the local population. Our water supplies being well protected, or the drinking water sterilized by boiling, very little typhoid in the service is water borne. The disease is introduced in other ways, sometimes, no doubt, by chronic bacillus carriers, but more often by incipient and mild cases among recruits or from contact with cases among the civil population already existing in the district. The studies of small epidemics made in the last few years point to the mild or walking case as the chief source of danger, and though in the service several thousand examinations have been made of the stools and urine of typhoid convalescents, no chronic bacillus carriers have been discovered. This is in practical agreement with the experiences of the Spanish War, when about one half the cases were diagnosed malaria; at the present time a provisional diagnosis of influenza is often made, but as no disinfection or isolation is instituted until typhoid is suspected, the interim provides opportunity for the infection to spread by contact. The cooks, assistants and mess hall attendants being detailed by roster from the entire company, sooner or later a mild case of typhoid has access to the food supply, and under such conditions experience teaches that many cases may occur. In the Spanish War we had no less than 20,738 cases with 1,580 deaths in an army of 107,973, or approximately 1 case to every 5 soldiers. The deaths from this cause constituted 86% of the total mortality of the war. In the Boer War the British had 31,000 cases with 5,877 deaths. In the Franco-Prussian War there having been 73,396 cases and 8,739 deaths among the Germans alone, typhoid is to be charged with 60% of the total mortality of that war. In the Northern Army during the Civil War we know of 80,000 cases. Such experiences would indicate that in campaign this disease is the greatest enemy with which we have to deal.

* Read at the meeting of the Boston Medical Library and the Suffolk District Medical Society, Dec. 7, 1910.

This being the condition confronting us, it is a serious question for us to decide which of the available prophylactic measures is the most suitable. The answer is, of course, self-evident, and while we cannot afford to neglect any measure, our chief dependence rests on immunizing each individual, and the very fact that the usual precautions against typhoid are impossible of execution enhances the value of vaccination.

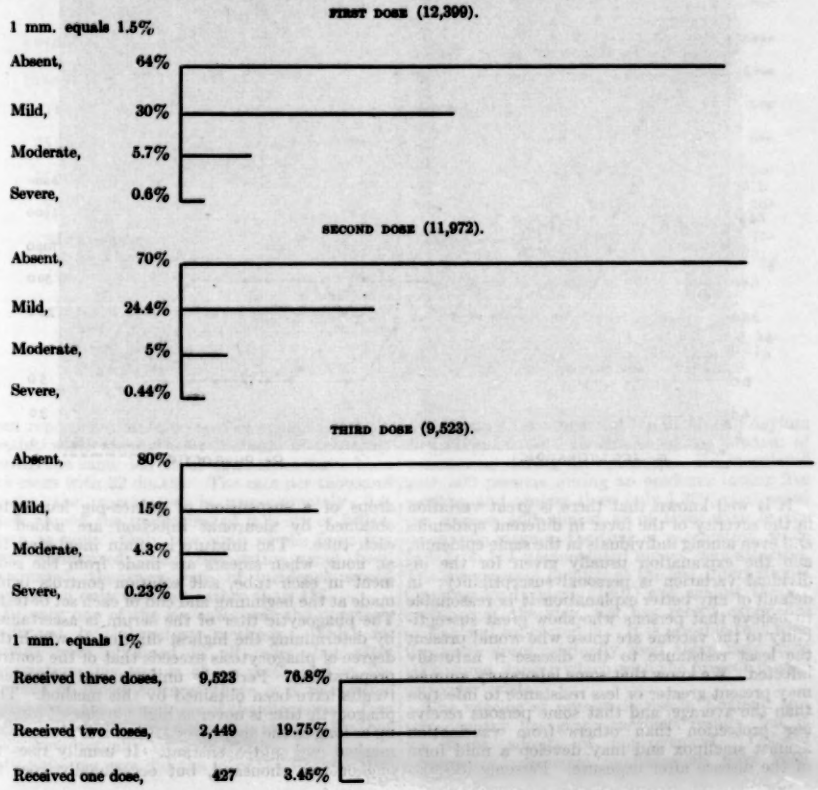
Experience with vaccines in general and with typhoid vaccine in particular has shown the possibility of increasing the individual resistance to infection. As far back as 1886 Simmons and Frankel [1] immunized small animals with living cultures and Beumer and Piper [1] immunized mice. Chantemesse, Widal, Sanarelli [1] and others very early began investigations of typhoid prophylaxis by immunization. Little or nothing came of these experiments, largely because of the impracticability of using living bacteria on men. It was not until 1892 that Brieger, Kitasato and Wassermann [2] found that the use of living bacteria was unnecessary and that a high degree of immunity could be produced by killed cultures. In 1893 and 1894 Pfeiffer reported his investigations on the nature of the immunity in typhoid and cholera and elaborated a test for the presence of protective bodies in the serum which has become classic under the name of the Pfeiffer phenomenon. Soon after, in 1896, owing to the discovery of agglutinins by Grubler and Durham, our knowledge of typhoid immunity advanced rapidly. In the same year Pfeiffer and Kolle [3] immunized two men against typhoid and made complete and comprehensive studies of the blood changes following inoculation with killed cultures. Their work showed, according to present laboratory standards, the identity of the immunity produced by vaccination and by an attack of the fever, both agglutinins and bacteriolysins being greatly increased. A few weeks before Pfeiffer and Kolle's experiments became public, Sir A. E. Wright,[4] at that time connected with the English Army, inoculated two men with killed typhoid bacilli, but his studies were apparently on the coagulability of the blood since no report was made of the specific changes in the blood serum. In the next year, 1897, he launched the present antityphoid campaign in a publication describing the inoculation of 18 persons. In 1898 he vaccinated 4,000 men of the British Indian Army, and in 1900, on the outbreak of the Boer War, the vaccination was carried out on troops destined for South Africa. Wright furnished some 400,000 doses, and it is understood that 100,000 men were inoculated one or more times.

While the results were unquestionably good, the incidence of the disease being diminished approximately one half, and the mortality nearly two thirds, they were not as satisfactory as had been expected. The effects of the inoculations in some organizations of the English Army in South Africa were, however, quite unsatisfactory, in a few instances it even seeming to do harm by apparently increasing the susceptibility to infection. This view being accepted by Wright [5] and explained as a manifestation of a negative phase in the progress of immunization, it, together with some unfavorable reports, led to a cessation of the work toward the end of the war.

The next extensive use of the measure was in the German Colonial Army in South West Africa during the Herero campaign from 1904 to 1907.[6] The army, being composed of but 16,500 men, was greatly handicapped by the spread of typhoid among them. The matter was laid before Prof. R. Koch, who advised prophylactic vaccination, but as the measure was entirely voluntary, only about one half the command, 7,287, accepted it. The same degree of protection was obtained as in the Boer War. This closes the first period in the history of typhoid vaccination. The present period began in 1904 with the work of Sir William B. Leishman, of the Royal Army Medical Corps, who published such remarkably good results in the *Corps Journal* in 1907 that our attention was again drawn to the matter.[7] In the summer of 1908 the writer was permitted to visit the laboratory of Colonel Leishman and given every opportunity to study his methods and results. It having already become apparent that some of the poor results obtained in the early days, being due to avoidable causes, it was now possible to prepare a much more efficient vaccine. Colonel Leishman [8] has recently stated his belief that much of the vaccine of earlier days was inert because of overheating during its preparation and that with proper care it is possible to produce a uniformly good and potent vaccine.

In the fall of 1908 we fitted up a special laboratory at the Army Medical School in Washington for the preparation of vaccine on a large scale, and in February of 1909 began the vaccination of all applicants. At first volunteers were obtained with difficulty and it was only through the loyalty of the medical officers in town, who came bringing their wives, children and servants, that we succeeded in arousing interest. In this way about 150 persons were vaccinated, almost all of whom became active missionaries in the cause. By the end of 1909 we had given 5,106 doses to 1,987 persons; of these 77% received three doses, 17% two doses and only 6% failed to take more than one. During the present year, 1910, we have given up to Dec. 1, 1910, 39,000 doses to 14,286 persons, and although the vaccine has been administered by several hundred physicians located in many different places, no untoward results have been reported from the entire series.

The immediate effect of the vaccination is to produce both a local and general reaction. The local reaction is subject to much less variation than the general. The sensation arising from the injection is no more uncomfortable than from any other hypodermic injection as the suspension is made in normal salt solution and the quantity is quite small. The site of inoculation is the upper arm at the insertion of the deltoid, and after four to five hours it becomes red, swollen and tender. The area involved is often as large as the palm of the hand; occasionally the axillary glands are enlarged and tender on the day following. After

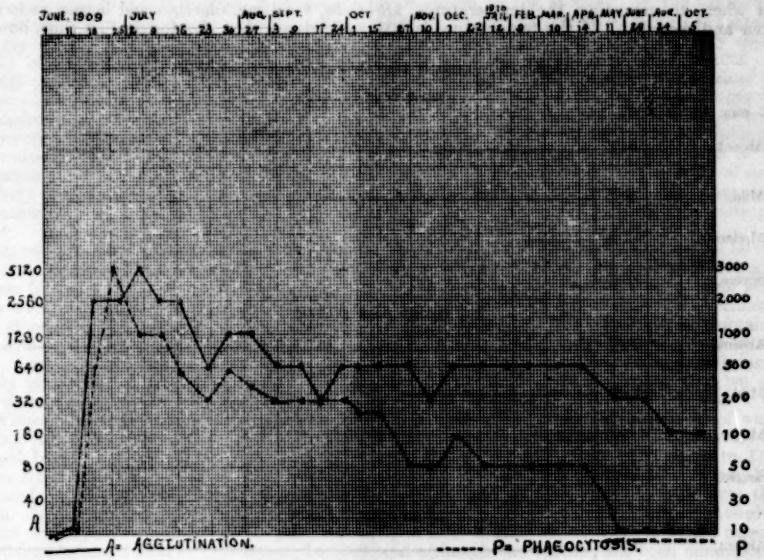


forty-eight to seventy-two hours the inflammatory symptoms begin to subside, soon disappearing completely.

The general reaction is not nearly so uniform in its manifestations; occasionally it begins in thirty minutes to an hour after inoculation, although in the great majority of instances no symptoms appear until after five or six hours. The principal symptoms are headache and malaise, and although they may be extremely mild, they are rarely absent. The average reaction gives rise to symptoms not unlike those felt during the first few hours of an acute cold. In order that we may know the immediate effects, all general reactions have been recorded and grouped in four classes; the first group comprises those cases in which the general reaction was absent; the other groups are called mild, moderate and severe. All men vaccinated are directed to report to the surgeon if unable to attend to the usual duties, and when so reporting the temperatures are taken and recorded. If the temperature is 103 or over the reaction is classed as severe; if between 100 and 103, moderate; if above normal and below 100, as mild; if no temperature is noted the reaction is considered absent unless the man complains of headache and malaise, when it is classed as mild. A classification based on temperature is not altogether satisfactory, but for obvious reasons it is all that is possible.

The results to date have been tabulated and are given below.

There is no discomfort aside from a tender arm when the general reaction is absent, and in the mild cases the symptoms are not particularly unpleasant and these two groups constitute about 95% of all reactions recorded. The moderate and severe reactions together make up the other 5%, and very few of them are really troublesome. The response has occasionally been so severe, exhibiting not only a high temperature, but also chills, vomiting, diarrhea and herpes, as to cause some alarm when seen for the first time, but even



General Reactions Following Vaccinations, 1910.

in these cases the symptoms last but from twenty-four to thirty-six hours and leave no trace with the exception of a few pounds lost in weight. Very few individuals have refused to continue with the immunization because of the discomfort; changes of station, discharge from the service, desertion, etc., are the principal causes for the failure to receive all three doses. We have taken especial pains to secure full reports of all severe reactions, as it was realized that if many occurred it would be increasingly difficult to induce men to volunteer, and for this reason it is gratifying to find so few have been reported. We do not now know the reasons for severe responses nor when to expect them; the fact that a man has already had typhoid seems to increase the chance of having a severe reaction, and in 124 such cases the records show a distinctly higher percentage of marked reactions.

crasy is a condition so generally recognized that we are not surprised to encounter it in this connection.

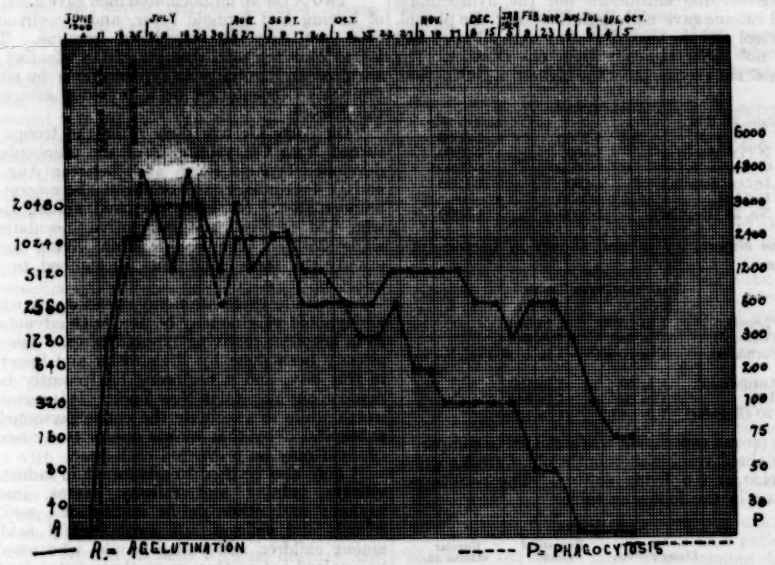
The late results of vaccination are shown in the accompanying charts. Agglutinins begin to appear on the fifth to eighth day, and increase rapidly. The Widal reaction is often present in dilutions of 1-5000 and occasionally the serum develops a titer of 1-10000 or even 1-20000. Only rarely does it fail to exceed 1 in 5 or 600. The rise in opsonins follows quickly and their increase is just as striking as the development of agglutinins. We have not used the opsonic index of Wright as we have found the dilution method of Neufelt both satisfactory and simple. The serum is diluted as for agglutination, and to measured quantities of each serum dilution is added a couple of drops of bacterial emulsion. The mixture is incubated for an hour at 37° C. when two

It is well known that there is great variation in the severity of the fever in different epidemics and even among individuals in the same epidemic, and the explanation usually given for the individual variation is personal susceptibility; in default of any better explanation it is reasonable to believe that persons who show great susceptibility to the vaccine are those who would present the least resistance to the disease if naturally infected. We know that some laboratory animals may present greater or less resistance to infection than the average, and that some persons receive less protection than others from vaccination against smallpox and may develop a mild form of the disease after exposure. Personal idiosyn-

drops of a suspension of guinea-pig leucocytes obtained by aleuronat injection are added to each tube. The mixture is again incubated for an hour, when smears are made from the sediment in each tube, salt solution controls being made at the beginning and end of each set of tests. The phagocytic titer of the serum is ascertained by determining the highest dilution in which the degree of phagocytosis exceeds that of the control preparations. Perfectly uniform and consistent results have been obtained by this method. The phagocytic titer is never as high nor does it remain up as long as the agglutinative, but it is always well marked and quite constant. It usually rises to one or two thousand, but occasionally goes to

five or even six thousand; it drops at first rapidly and then more slowly, but may still exceed the normal after the lapse of a year.

Bacteriolytic tests have been made from time to time, but no entirely satisfactory method has been found which will give consistent results over a long period. A mere statement of the bacteriolytic titer of a serum has, in our experience, very little value, since it depends almost as much on the culture used for the test as on the serum to be tested.



If the usual complement fixation test is used it can be shown that the serum after vaccination contains an antibody which will anchor complement just as after typhoid itself.

Among the 14,000 persons vaccinated there have been reported to date 6 cases of typhoid with no deaths, while among the remainder of the army during the same length of time there have been 418 cases with 32 deaths. The rate per thousand among the vaccinated is approximately 0.4, while among the unvaccinated it is six or fifteen times as high. Only one sixth of the force has been immunized; had the entire army been vaccinated, the same rate of incidence would have given only 36 cases rather than 418.

In only one of the six cases was the diagnosis confirmed by laboratory methods; Widal reactions were obtained in all cases, but after vaccination this test is of no value and in the absence of blood cultures there is a reasonable doubt as to the correctness of the diagnosis. Two of the cases were so mild that it is improbable that they were actually typhoid fever.

In only one case did the fever occur soon after vaccination and in this instance the infection was probably acquired between the first and second doses; when the time came for the third dose the man was sick in hospital. This might be regarded as an instance of increased susceptibility, but as the man crossed the continent during the interval, the infection was probably a coincidence. None of the nine others vaccinated at the same time contracted the disease, while one other case developed among the unvaccinated men of the same regiment.

Aside from this no cases bearing on the negative phase have been reported. The fear of a dangerous negative phase being so widespread has deterred our medical officers from vaccinating in the presence of an epidemic.

Cullinan's [9] experience at the Richmond Asylum in Dublin is proof conclusive of the wisdom of vaccinating during an epidemic. He inoculated over 500 persons during an epidemic lasting five months, and among these only 1.36% contracted the disease, and almost all of these were in the incubation stage at the time of vaccination, while 14.9% of 114 uninoculated nurses were attacked. The concensus of opinion at the last International Congress for Hygiene (1907) was against the acceptance of the idea, nor has recent experience in England supported it. It is possible that with the large doses originally used there may have been some danger which with the present dosage no longer exists.

The vaccine at present in use in England and this country has given excellent results, but it no doubt admits of improvement. Colonel Leishman's [8] principal modifications have been

the reduction of the temperature used in killing the cultures from 60° to 53° and the addition of the lysol only after the vaccine has been cooled. It is not surprising that it has occurred to others to omit heat altogether since the antiseptic is in itself able to effect complete sterilization. Semple and Matson used 0.5% phenol, believing that heat diminishes both the immunizing and the keeping properties of the vaccine. A phenolized vaccine prepared by them without the use of heat was still potent after two years.

In December, 1909, we sterilized a series of vaccines by the addition of phenol, tricresol, formalin, antiformin, absolute alcohol and hydrochloric acid, and in March, 1910, inoculated a number of rabbits.[10]

Neither the antiformin nor the hydrochloric acid vaccine gave high agglutinations; the phenol, tricresol and the heated vaccine were all good and did not differ radically from one another. The formalized vaccine gave the highest agglutination.

AGGLUTININS.

| March 23, 1910. | | April 6, 1910. |
|---|---|---|
| A (Phenol), | 1-2500 | 1-5000 |
| B (Tricresol), | 1-5000 | 1-2500 |
| C (Formalin), | 1-10000 | 1-20000 |
| D (Antiformin), | 1-160 | 1-1280 |
| F (Hcl), | 1-2500 | —— |
| No. 20 (Regular), | 1-2500 | 1-5000 |

Its superiority is also shown in bacteriolytic tests.

BACTERIOLYTIC TESTS.

| | March 24. | April 1. |
|---|---|---|
| A (Phenol), | 1 in 1,280 | 1 in 640 |
| B (Tricresol), | 1 in 640 | 1 in 640 |
| C (Formalin), | 1 in 10,000 | 1 in 40,000 (higher not made) |
| D (Antiformin), | 1 in 40 | 1 in 160 |
| F (Hcl), | 1 in 20 | 1 in 640 |
| No. 20 (Regular), | 1 in 640 | 1 in 1,280 |

A second experiment was arranged to compare a formalized vaccine six months old, a fresh regular vaccine and a living culture. The results are shown in the following table.

AGGLUTININS.

| | Living culture. | Formalized vaccine. | Regular vaccine 32. |
|---|---|---|---|
| July 5, 1910, | 1 in 1,280 | 1 in 1,280 | 1 in 320 |
| July 13, 1910, | 1 in 5,000 | 1 in 10,000 | 1 in 5,000 |
| July 21, 1910, | 1 in 10,000 | 1 in 10,000 | 1 in 10,000 |
| Aug. 6, 1910, | 1 in 2,500 | 1 in 5,000 | 1 in 5,000 |

In this experiment the formalized vaccine made rather the best showing and both vaccines proved equal if not superior to living cultures. Phagocytic determinations point to the same conclusions.

PHAGOCYTOSIS.

| | Living culture. | Formalized vaccine. | Regular vaccine 32. |
|---|---|---|---|
| July 5, 1910, | 1 in 100 | 1 in 100 | 1 in 100 |
| July 13, 1910, | 1 in 500 | 1 in 500 | 1 in 500 |
| July 21, 1910, | 1 in 500 | 1 in 1,000 | 1 in 1,000 |
| Aug. 6, 1910, | 1 in 500 | 1 in 1,000 | 1 in 1,000 |

We may then conclude that a new formalized vaccine is the most effective and that one six months old is equal in power to a regular vaccine of two months.

Our tests of formalized vaccine are still in progress, but from present indications, although there is some deterioration with age, it seems to give greater protection than any other.

A recent experience illustrates strikingly the efficacy of vaccination.[11] On June 14, ten days prior to leaving Washington for Gettysburg maneuvers, 92 members of Company A, First Battalion of Engineers, received the first antityphoid vaccination. On July 2, 52 of the above men received the second vaccination, and July 16, 51 of these received the third. Of the remaining 26 men of the command, a few refused vaccination and others were temporarily absent or on detached service when the first inoculation was given.

"Two of the 26 uninoculated men gave a history of having had typhoid fever, and by virtue of that fact may be considered immune. This leaves 24 of the total strength of 118 who had not acquired an immunity to typhoid fever by either preventive inoculation or a previous attack of the disease.

"On Aug. 11, five days after the troops returned from Gettysburg, 2 of the uninoculated developed typhoid fever, and, between Aug. 20 and 23, 4 secondary cases occurred, also among the uninoculated. No cases occurred among those who had received the preventive inoculations, while 25% of the non-immune, living under exactly the same conditions, succumbed to the infection."

In civil life there are many occasions on which antityphoid vaccine may be used with advantage, as in hospitals receiving typhoid cases. This has already been done by Richardson and Spooner, in this city, and a beginning has recently been made in one hospital in New York. It is certainly worth while to vaccinate the entire personnel of a hospital if by that means one or two cases of typhoid may be prevented each year.

It may also be used to advantage in industrial villages, mining and railway camps, insane asylums and other public institutions, and in schools and colleges. A most fruitful field is among children and young people, who may be immunized before they go to the country for the summer vacation. In our experience the reactions among children are much less marked than among adults, and often, especially among the younger ones, there is no inconvenience whatever.

I wish to add a few words on the subject of the treatment of typhoid fever by vaccine.

Capt. A. B. Smallman [12] reports 36 cases treated in India with 3 deaths, giving a death-rate of 8.3%, which is much lower than the usual rate. Of the 3 deaths, 2 occurred in fulminating cases about a week after admission and after the administration of only one dose of vaccine. Doses of 300 to 400 million bacteria were used on every third or fourth day.

Dr. Semple [13] reports 11 cases. Nine were treated with vaccine, but 2 refused to have it administered; of these 2 cases, 1 ended fatally. All of the 9 vaccinated cases recovered. He believes the method to be free from all risk, easy to

carry out, producing no apparent disturbance in the patient's condition or interfering with any other treatment deemed advisable. His charts show a well-marked increase in the antibodies of the blood after vaccination.

Nichols,[14] in 1909, reported 11 cases. There were no deaths, and the cases were of average severity. One had mild delirium, one intestinal hemorrhage and relapse, one relapse and two were prolonged to thirty-one and thirty-three days. He considered the results inconclusive; they show, however, that the vaccine even in large doses produces no bad effect. Relapses were not prevented, but to what extent the favorable course in most of the cases was effected by the inoculations is undetermined. At the same meeting Behrend reported 12 cases; Ramsburg, Ruffin and French, one case each. A total of 26 cases with no deaths are reported in this article and the discussion.

Watters and Eaton[15] report 30 cases with 2 deaths. One was, however, beyond help when the treatment was begun. The same authors report 4 additional cases without any deaths in a later communication. Their experience leads them to remark that "it might be of further interest to note that during the year 1908, out of 77 cases of typhoid fever in the hospital, 31 were treated by vaccines, the remainder receiving only the regular routine treatment of dietetic, hygenic, hydrotherapeutic and drug measures here in vogue. No selection of patients was made, all coming into certain services, being taken whether mildly or severely ill. As a result, in no case was any one observed to be injured by the vaccine, while the mortality among those thus treated was 3.2% as compared with a death-rate of 11.1% in those not receiving it. About 75% of the cases were favorably influenced."

Capt. H. T. Wilson,[16] R. A. M. C., reports 6 cases with no deaths. In this series the disease appears to have been shortened and the longest duration of the fever was seventeen days. He used large doses, 250 to 1,000 million bacteria. One case had three and the other two doses.

Hollis[17] reports 11 cases with no deaths. He used doses ranging from 1 to 300 million every second or third day; aside from this the patients, who were not selected cases, received no other treatment. During the same season 25 cases were treated with the customary hydrotherapeutic measures and 4 deaths occurred. Hollis notes that the agglutinins were uniformly increased by the vaccine. Relapses were more frequent, 30% as compared with 10% in the unvaccinated. In a few cases the febrile course seemed shortened, but the temperature was equally high in both series, and hemorrhages occurred with the same frequency. On the other hand, headache, gastro-intestinal symptoms and toxemia were less frequent and convalescence more rapid.

He predicts a brilliant future for vaccine treatment.

The total number of cases here collected is 118, with 5 deaths, giving a mortality of 4.23%, which is distinctly lower than has been obtained with any other treatment. This collection of cases is altogether too small from which to draw conclusions, but the treatment has made a favorable impression on nearly all using it.

Pascarolo and Quadrone have treated 20 cases with a living attenuated typhoid bacillus. The cases were selected as being exceptionally severe and the results were satisfactory.

Is there any theoretical basis for the use of vaccines in typhoid? The question is frequently asked and as often answered in the negative. Theobald Smith[18] has stated the problem concisely in the following words: "The presence of virulent living bacteria makes it seem absurd to add dead ones. Why is not the former stimulus enough? Theoretically no advantage can be expected from adding more toxins."

Cases do improve, however, under vaccine treatment and there must be a difference between the stimulus exerted by living virulent organisms and dead vaccines.

The first difference is in the use of dead bacteria; the dose can be controlled and there is no cumulative effect. The second difference is in the use of the subcutaneous connective tissue in inoculations. Typhoid is largely a disease of the lymphoid tissues, which is the place of least resistance in the body. This is equivalent to saying that the lymphoid tissue is the least able of any to form destructive antibodies. The connective tissue, on the contrary, has the power of forming them in great quantities, and they are rapidly carried to all parts of the body by the blood stream. It would seem possible to reinforce the immunity reaction by bringing into the struggle tissues not ordinarily involved.

Another difference is in the strain of the organism used, — an old avirulent culture. In other words, in using vaccines in the treatment of typhoid we need not necessarily inject additional toxins. Our cultures have largely lost the power to produce toxins. We are injecting antigen, which in this case seems to be different from the toxin, and it is capable of stimulating the immunity reaction in the body of a patient without at the same time overwhelming him with poison.

Vaccines cannot be expected to stimulate a patient already profoundly toxic, nor will they improve complicating conditions due to secondary invaders, but in pure typhoid it is not illogical to expect them to benefit.

The following conclusions seem to be justified.

Typhoid has invariably appeared in armies in the past and may be expected in the future.

The usual prophylactic measures are only partially available in camps.

Vaccination is simple and harmless and wherever used has reduced the incidence and mortality of typhoid.

The immunization of every individual in the army is perfectly feasible, and it offers the greatest hope of freedom from this plague in the future.

Antityphoid vaccination has long since passed the experimental stage. Since 1904, 60,000 men have been vaccinated in India, over 7,000 in

South West Africa, and over 14,000 in the United States and in no case has any harm followed its administration. The time has come when its use should be extended, not merely in the military services, but also among the civil population.

## ANTITYPHOID INOCULATION AS INTRODUCED INTO CERTAIN TRAINING SCHOOLS FOR NURSES IN MASSACHUSETTS.*

BY MARK WYMAN RICHARDSON, M.D.,
*Secretary of the State Board of Health of Massachusetts;*
AND
LESLEY H. SPOONER, M.D., BOSTON.

THE subject of typhoid fever at the Massachusetts General Hospital, with especial relation to its bacteriology and its immunity, had been the chief study of one of the writers (M. W. R.) for twelve years when, in 1909, it was decided to make a beginning at least with an investigation of specific antityphoid inoculation as a method of prophylaxis against the disease.

Experiments with specific sera, filtrates, residues and vaccines had not led to any very remarkable results in the treatment of the declared disease, although the use of these products for the possible prevention of relapses and recrudescences had given results of a distinctly encouraging character. There seemed, however, good reason to believe, especially through the observations of Wright upon the British troops, that in prophylaxis, specific inoculation might have a field peculiarly successful. The unusual incidence of the disease among nurses had also been noted.

Joslin and Overlander [1] had found that "during the years 1902–1906 inclusive, twenty-six nurses contracted typhoid fever while working in six hospitals. The average number of nurses employed each year in these hospitals was 322 and the total number of cases under their charge, 2,988. In other words, for each 114 cases of typhoid fever treated, one nurse came down with the disease. The typhoid morbidity rate for the nurses in these same hospitals was 161 per 10,000 living instead of 20 per 10,000 living, which is approximately the typhoid morbidity rate for the whole population of the state."

As a result these investigators concluded that "the hospital nurse in Massachusetts is about eight times as liable to contract typhoid fever as the ordinary citizen."

Dr. Spooner [2] also, at my suggestion, looked up the cases at the Massachusetts General Hospital and found that, for the ten years previous to 1909, anywhere from two to six of the nurses had come down annually with typhoid fever.

In view of these facts it was natural, therefore, that, in inaugurating the use of specific inoculation, appeal should be made first to the members of training schools for nurses. A start was made at the Massachusetts General Hospital in 1909. The nurses were called together and the situation was placed before them in brief. A call for volunteers was then made and met with unexpected success. The work thus begun at the Massachusetts General Hospital has been continued along similar lines at nine other institutions. The inoculating has been done generally by locally interested physicians under the direction of one of us (L. H. S.). Indeed, the interest and co-operation of the hospital authorities and local physicians has been most hearty and it gives us great pleasure publicly to acknowledge this fact, for without this co-operation no progress could have been made. The following table shows the institutions which have adopted the procedure and the number of individuals inoculated:

| Hospital. | Inoculator. | No. of Cases. |
|---|---|---|
| Massachusetts General Hospital. | (L. H. S.) | 153 |
| State Infirmary at Tewksbury. | H. R. Coburn, M.D. | 56 |
| Waltham Hospital. | R. E. Wilson, M.D. | 32 |
| Salem Hospital. | A. N. Sargent, M.D. | 24 |
| New England Hospital for Women. | M. E. Morse, M.D. | 12 |
| Children's Hospital. | W. P. Lucas, M.D. | 10 |
| Boston State Hospital. | M. M. Canavan, M.D. | 40 |
| Danvers State Hospital. | H. M. Adler, M.D. | 10 |
| Brockton Hospital. | A. L. Beals, M.D. | 17 |
| Worcester Memorial Hospital. | E. B. Bigelow, M.D. | 19 |
| Miscellaneous cases. | (L. H. S.) | 32 |
| | | 405 |

As regards the preparation of the vaccines, the following points are of interest:

The culture used has been an old stock culture, and one utilized for a number of years in the laboratory for the making of Widal reactions. The organisms are grown on agar, suspended in salt solution, heated to 53° C. for one hour, and counted with the use of a Zeiss blood platelet counter. Lysol, ¼ of 1%, is added to prevent the growth of any accidental contaminating organisms. The inoculations are given on the outer surface of the left upper arm at the insertion of the deltoid muscle.

The number of inoculations given has been four, at five-day intervals. In the beginning the initial dose was placed at 50 millions and increased gradually up to a maximum of 200 millions. In

* Read at the meeting of the Boston Medical Library and the Suffolk District Medical Society, Dec. 7, 1910.

[1] BOSTON MED. AND SURG. JOUR., vol. clvii, p. 247, Sept. 26, 1907.

[2] Am. Jour. Pub. Hyg., vol. xix, no. 4, August, 1909.

the more recent series we have increased the dose so that, although the initial dose is still 50 millions, the maximum is now 300 or 400 millions. The local and general reactions experienced by the individuals inoculated have varied in severity. The experience among those inoculated at the Massachusetts General Hospital was approximately as follows:

Ninety per cent showed at most a very slight reaction, and 10% showed a moderate reaction. In only one instance was it necessary for a nurse to give up her accustomed duties, and then only for a period of twelve hours. The specific effect of the inoculations upon the blood reactions, as previously reported, was as follows:

Out of the first 100 cases inoculated at the Massachusetts General Hospital, 94.2% developed in their blood an agglutinative strength of 1 to 25, and 80.6% showed a strength of at least 1 to 50.[1]

In contrast to the experience of the ten previous years, 1909 and 1910 have shown no cases of typhoid fever among the nurses at the Massachusetts General Hospital, unless the following instance may be considered a typhoidal infection:

A nurse who had received regular inoculations ten months previously suffered from an illness characterized by a temperature of 101.8 and all the symptoms of acute but mild infection. Physical examination as well as bacteriological investigation of the blood and feces was negative. The agglutination test, however, was positive at first in a dilution of 1 to 100, and two days later in a dilution of 1 to 200. Her temperature fell to normal on the third day and remained so. In looking back over the history of this case, it seems that two weeks after her series of inoculations, ten months previously, the agglutinative strength of her blood was 1 to 100. Whether the increased agglutinative strength on the third day in the subsequent infection can be regarded as a sufficient evidence for the diagnosis of typhoid fever must be considered doubtful. Even if we admit, however, that this case was one of typhoid fever, its extreme mildness is suggestive. Curiously enough, the same individual is now suffering from an attack of measles and the blood shows once more a typhoid reaction in a dilution of 1 to 100.

Among the individuals inoculated in hospitals other than the Massachusetts General Hospital it is stated that local or general reactions were absent or slight in 83% of the cases; of moderate severity in 13%; and more severe in 4%. Agglutination tests were performed in a few cases in two hospitals and all those inoculated at a third. Those in which the blood was investigated showed strengths ranging from 1 to 50 to 1 to 600.

Among the nurses inoculated in hospitals other than the Massachusetts General Hospital, two cases of typhoid fever have developed. The first case showed its earliest symptoms shortly after the first inoculation had been given. Mild fever was present for two weeks and convalescence is now in progress. In this hospital an epidemic among the nurses was already in progress and there can be little doubt that this nurse received her first inoculation during the incubation period.

The second case presents many points of interest. The patient was a woman who had been nursing two cases very sick with typhoid fever. Both were extremely delirious, absolutely incontinent and both subsequently died. The attending nurse received three inoculations with a vaccine similar to that used upon eighteen of her associates. None of the inoculations produced more than a slight reaction. Thirteen days after her first inoculation, however, and three days after her last inoculation, she first showed signs of a mild typhoid infection. Her temperature, however, never exceeded 102.5° and she suffered no interruptions in her convalescence. It seems reasonable to suppose that this nurse also was inoculated during the incubation period of the disease. In view of the fact that she was probably infected with organisms which were responsible for the death of two other individuals, it may not be entirely unreasonable to assume that the severity of her infection was attenuated by the inoculations which she received. In any case, these two histories serve very well to demonstrate that there is no danger in inoculating those individuals who in the near future are likely to be exposed to infection. In other words, the danger to be apprehended by what was designated by Wright as the negative phase of immunity said to follow bacterial inoculation seems to have no substantial basis in fact. The practical importance of this observation lies in the fact that, in the presence of a local epidemic of typhoid fever, widespread inoculation might be advised and carried out without fear that the individuals inoculated would thereby be made more susceptible to the disease than before.

As previously stated, the local and general reactions following inoculation are in the majority of individuals inconsiderable. It has been the experience, however, of one of us (L. H. S.) that latent or chronic foci of infection of non-typhoidal character may be lighted up by the typhoid inoculations. There were four such instances. First, chronic infectious arthritis of the knees; second, subacute urethritis; third, chronic infectious arthritis of the ankles, associated with flat foot; and fourth, chronic cholecystitis. No permanent damage was done, to be sure, but these recrudescences, by their temporary discomfort and inconvenience, were sufficient to make precautions advisable. Before inoculation, therefore, it is best to inquire somewhat into the previous history in search of old or latent infections, and to refuse to inoculate all persons showing a temperature over 99°.

In this connection it is interesting to note that just as latent infections seem to be rendered acute temporarily by typhoid inoculation, so it has also been observed that a typhoid agglutination reaction, when once established in the body by specific inoculation, may be stimulated to reappearance by other infectious processes. Four instances have been seen in which strong agglutination strengths have been found in the blood long after inoculation and associated with such

[1] Boston Med. and Surg. Jour., vol. clxii, p. 37, Jan. 13, 1910.

diseases as grippe, tonsillitis, pleuro-pneumonia and measles.

Our experience, therefore, covers 1,588 inoculations practiced upon 405 individuals. As yet there have been no untoward results, and we believe that the inoculated individuals have acquired an increased resistance to typhoid infection which will last them for several years at least. We expect in the coming year to extend the influence of these inoculations, especially among nurses and others attendant upon the sick. Furthermore, we have strong faith that the procedure will, within a short time, find increasing favor with the general public, which, exposed as it is to many sources of infection, is in great need of specific protection.

## THE FRESH-AIR SCHOOL.*

BY JAY PERKINS, M.D., PROVIDENCE, R. I.

DURING the past few years we have heard a great deal about the conservation of our natural resources, and we have come to realize that as a nation we have been very prodigal of such resources as land, lumber, coal and iron. The public has not yet, however, though a beginning is apparent, come to realize how prodigal we are of the greatest of all natural resources, the health of the community. Those who are making a study of public health fully realize that the former dreaded diseases, smallpox, typhoid fever, yellow fever, cholera, plague, malaria and the contagious diseases of childhood are controllable and are coming under control. Typhoid fever was formerly prevalent every summer in most large centers of population. The proper disposal of sewage and the purification of water supplies has largely obliterated it. When a large number of cases of typhoid fever now appear in the same locality in successive years some one is almost or quite criminally negligent. The problem of typhoid fever was comparatively simple — proper disposal of sewage and purification of water and milk supplies.

With tuberculosis we have a somewhat similar problem, but one which is much more complicated, and yet tuberculosis can be brought under control as is typhoid fever to-day. No case of tuberculosis arises except following infection from a preceding case, the infection here usually coming through excretions from the mouth of some one having tuberculosis. The control, however, of the excretions from the mouth is a very different problem from the control of the excretions from the bowels, the usual source of infection in typhoid fever. Another great difference in the two diseases is the method of onset. In typhoid fever we have an incubation period of about two weeks and the disease runs its course in a few weeks more. With tuberculosis the germs may be taken into the body and remain inactive for many weeks, months or even years, probably.

The tubercle bacillus is a true parasite. So far as known it does not multiply outside of some animal body, and in nearly all instances the bacilli causing consumption come from some other human being. Once lodged in the human body their future existence is purely a biological question and their development depends upon the relative vitality of the body and the bacilli. If the body has sufficient resistance to this organism, the bacilli will be killed before multiplying. No one is sufficiently strong to withstand infection with tubercle bacilli if a sufficient number of virulent germs gain access at the same time. This, however, would refer to artificial and not to natural infection. If the body is not sufficiently strong to at once kill any tubercle bacilli with which it is infected, these bacilli either lie dormant, giving us latent infection; or multiply sluggishly, giving subacute infection; or multiply rapidly, as in an acute infection; or the body is shortly overwhelmed, as when the germs are distributed throughout the whole body. The vitality of the host and of the parasite vary inversely, and thus it is that a body may hold the parasite in subjection indefinitely or a sudden weakening of the vitality of the body may allow the parasite to become more virulent and still further weaken the body.

Laboratory workers are beginning to be able to find substances in the blood and tissues of the body which are the elements that resist infection, but even the finding of these elements does not change facts which have for a long time been known, — that the real strength of the human body must depend upon the taking into the body and the right use in the body of oxygen and nourishing food, and upon the proper regulation of the functions of the body by necessary exercise, sleep and suitable clothing, and upon the keeping out from the body all poisonous substances.

I have taken your time with these statements because I consider them as essential for a full understanding of the Fresh-Air School and of the ultimate ends we have in view through the establishment of these schools; and let us at the beginning have a clear understanding that these are fresh-air schools and not strictly schools for the tuberculous. Children having active tuberculosis should never be permitted in the public schools. They should not be allowed to attend public school for their own sakes and I would keep them out on this ground. The fresh-air schools of the present day are for any children physically below par whether they have latent tuberculosis or not. The real relation of tuberculosis to the fresh-air school should be that the widespread campaign against tuberculosis has given a stimulus for more rational methods of living and that the majority of physically imperfect children, and in many instances the apparently perfect children, are infected with tuberculosis. The real object of these schools is both to conserve the health of the individual and to give the state better returns for the money spent in educating its children as much as it is to help stamp out the disease tuberculosis.

* Read before New England Association of School Superintendents, Boston, Nov. 11, 1910.

Tuberculosis being the stimulus which has brought about the establishment of these schools, we will first consider them in reference to that disease. You may think that but few pupils in our public schools are infected with tubercle bacilli. If so you are mistaken. We now have a a test which shows with reasonable accuracy whether or not a person has been infected with tubercle bacilli. With adults this does not mean much because most adults have been at some time infected. With children, however, it means a good deal, for almost no child is born with tuberculosis. As showing the frequency of tuberculous infection in children, and the age at which they become infected, we now have the results of numerous investigations. One series of 509 children who came to public hospitals for treatment for diseases other than tuberculosis were examined by the tuberculin test and positive reactions were obtained in 271 children, the proportion of positive responses increasing from 9% at the age of two to 51% at six, 85% at ten and 93 to 95% between eleven and fourteen (Vienna). Another investigation carried on in the Children's Clinic at Vienna showed that in a series of 401 autopsies of children, 160, or 40%, were found affected with tuberculosis. Of these last many came to the hospital because of tuberculosis, but in another clinic to which children were brought for acute illnesses and to which healthy babies were brought for observation and in order that the mothers might be taught to care for them, the tuberculin test was used. In the first two years no reaction was found. The increase in the number of reacting children of more advanced years was nearly as high as in the first group and reached 70% in the tenth year. These results, however, were obtained in Vienna, where tuberculosis is more prevalent than with us.

In Paris a careful examination was made of all the school children in a certain ward. They found that out of 896 children, 141 were affected with latent but unmistakable tuberculosis, 14% of the boys and 17% of the girls being affected, and this was by ordinary examinations and not by the use of the tuberculin test.

In New York City, 2,295 school children were examined for tuberculosis, and 29% were found to be affected. In investigating the children of tuberculous parents in Boston 679 examinations were made, and definite signs of tuberculosis were found in 36%.

In New York City, in an examination of 150 children of tuberculous parents, in 51% definite signs of tuberculosis were found.

In Chicago, in an examination of 146 children of tuberculous parents, definite signs were found in 29%.

When patients have been under treatment for active tuberculosis, as in a sanatorium, they are discharged with the disease still active or with the disease arrested or as apparently cured. By "disease arrested" is meant that the patient's temperature has become normal, that he is not suffering from the poison of the disease, and that for some time there has been no progress of the disease, but the germs are still there, ready to become active upon slight provocation. By "apparently cured" is meant that the person has for some time been free from all symptoms of the disease, that the bacilli have been absent from the sputum for at least three months and that examination of the chest gives only the signs of a healed lesion, but we know that even here the germs are still present in the body and that absolute cure is a question of years, that in order to obtain an absolute cure the individual must live a life very similar to that under which he became apparently cured, or else the disease will again become active. A cause of the partial failure of our sanatoriums to accomplish that which was expected of them lies in the fact that so many of the patients after being apparently cured or having the disease arrested return to live and to work under improper conditions and the disease again becomes active.

A further study of the children who are infected with tuberculosis shows that during the later years of school life but a small percentage of those who react to tuberculin give evidences of active tuberculosis. The explanation of this is twofold: The infection in children is not usually of the lungs (any part of the body may be affected) and the body has sufficient resistance to hold the parasite in abeyance, and, secondly, where the body has not this resistance, the disease becomes active, the children are removed from the school and are found either in attendance at some hospital or in cemetaries.

It has been found that children with tuberculosis of the bones and of the glands (scrofula) are very amenable to treatment. Thus the Sea Breeze Hospital at Coney Island has obtained excellent results in treating these conditions, as found among the poor in New York, and in Rhode Island the Crawford Allen Hospital (a branch of the Rhode Island Hospital), located on the shores of Narragansett Bay, is obtaining results which a few years ago would have been considered marvelous. This work is, however, done at great expense, and even then only a slight proportion of the affected children can be treated. The general treatment at these institutions is simply an out-of-door life, good nourishment and good care.

Now we have the data necessary for a consideration of the relation of the public schools to tuberculosis. Children who are affected with tuberculosis are in the schools and must be in the schools. They are there as arrested, as apparently cured, or as latent cases, and, just as with the patients who leave the sanatoriums, whether they go on to complete recovery or whether they are to enter our hospitals and add to the already enormous burden of hospital maintenance, or prematurely enter our cemetaries and thus be a loss to the state as individuals upon whom the state has already spent considerable money, will depend to a large extent upon their environment and the teaching they receive in the schools.

Almost every community of any size is now spending a large amount of money in anti-

tuberculosis work in educating the public in regard to tuberculosis, in caring for those who are sick with tuberculosis and in improving the home conditions of the poor. A large part of the work is being done at the wrong end. It is like trying to put out a fire by fighting the smoke and the blaze instead of getting at the origin of the fire. The only real way to reform a man is to do it while he is a child, and with the children is where we must fight tuberculosis before we can eradicate it. How is the present school life meeting the problem? You know better than I do what the school life of the children is, and I have no criticism to make except as relates to fresh air. We all know how inadequate are all systems of ventilation when put to the test of a crowded schoolroom and when regulated by ignorant janitors. We also know that no system of ventilation, so far as concerns the purity of the air in the room, equals open windows. In the ordinary schoolroom this method of ventilation has, of course, great disadvantages and can be used in winter only at intervals and with the children moving about, marching or taking calisthenics, and so long as the present system exists it should be compulsory for the teachers to open the windows at stated intervals and have the children exercise in some way.

The object of the fresh-air school is to have the air of practically the same purity as the out-of-door air and at the same time have the ingress of fresh air so regulated that the exposure of all the pupils and in all parts of the room will be practically the same. That this is perfectly feasible, even in our New England winter climate, without undue exposure of the children, we have demonstrated for three winters in Providence, and the same fact is now being demonstrated in various other places, one of the best schools now being located in Pawtucket. I am speaking of the fresh-air school as a part of our regular school system and not as applied to patients who are actually sick. School work with these patients is being carried on somewhat in day camps, in sanatoriums and in hospitals for tuberculous children, as was done during the past summer in our own Crawford Allen Hospital.

I will speak but briefly of how our fresh-air school is carried on because so much has been printed in regard to it. The exposure of the open side or sides of the room should be chiefly south, as the blustering winds of winter are usually from some point north of east or west and our school year never includes the summer months. The feet of the children must be protected, and this we have found is best done, and cheaply done, by means of the sitting-out bag such as is commonly used in treating tuberculous patients. The body is never strengthened by suffering, and care must be taken that the children are perfectly comfortable. The children are seated with their backs to the open side of the room on account of their eyes, — the whole room being sufficiently lighted so that no shadow is cast, — and the back of the sitting-out bag is made sufficiently long so that it can come up over the back of the child in case a strong current of air comes into the room, and when needed heated soapstones are placed inside the bag at the feet. The children wear their caps and mittens when the weather is sufficiently cold to demand it except when the mittens are removed for written exercises. The children are given some form of nourishment, as hot milk or soup, at about ten o'clock. They bring a lunch with them which is eaten at about twelve o'clock, to which is added hot cocoa made with all milk and to which cream is added when served, and a hot pudding containing a large amount of milk and eggs, or a substantial hot stew. The lunch is served at a regular table, the children being taught to prepare the table, clear it and wash the dishes, this being done during the noon recess. They have to wash their hands and faces and brush their hair before eating, and cleanse their teeth after eating, and incidentally tooth brushes are introduced into homes where they were heretofore unknown. The noon hour is shortened and the school dismissed earlier than the regular schools that the children may get home before dark, since several come from some distance. And here I would make a strong plea for one session for all young children, say the first two or even three grades. It is successfully done in several progressive cities and should be done in all schools. In this case, too, the one-session plan has seemed to us to work better than to have part of the children go home for lunch and to go home later at night. In pleasant weather, especially in the spring and fall, they are encouraged to spend what may remain of the day in out-of-door play.

Another important thing in the success of this work is that the children are visited in their homes and the home conditions studied and improved. In many instances, even where ignorant parents object, the children insist upon having fresh air at night.

Now what has been the result of the fresh-air school? Children who could not attend the ordinary schools with any regularity because of ill health, and especially because of frequent colds, can attend this school regularly and, sometimes after part of the year, in other cases after one or two years in this school, have so improved in health as to be returned to the regular schools and attend them successfully, to make room for others who need the fresh air more, the school being an ungraded one and as such limited to twenty-five pupils. Some children who even if they attended the other schools regularly could not accomplish satisfactory work have here caught up with others of their grade and have gone back into their regular rooms with good standing. The children are examined at the tuberculosis clinic at the Rhode Island Hospital and at the school are under the medical supervision of one of the regular school inspectors, Dr. Ellen A. Stone. They almost invariably gain in weight; the oxygen-carrying power of the blood, as shown by hemoglobin tests, improves; the whole appearance of the pupils changes markedly for the better and the work is a grand success from all points of view.

The public gets better returns for the money spent purely from the educational standpoint, and the educational effect in the homes is of great value, fewer children become applicants for admission to hospitals, and I might here add that during the summer months many of these children are kept in the day camp. We look, however, for results far wider than is obtained in the individual schools. We want it impressed upon teachers to pay greater attention to the physical side of their pupils. We want to have all schoolrooms become, if not fresh-air rooms, at least reasonably ventilated rooms. We want to have the children taught the simple but essential rules of hygiene, not simply the ill-effects of alcohol and tobacco. We want them taught that many diseases, even so-called colds, are diseases which are transferred from one person to another and most commonly by secretions from the mouth and that the infection is usually taken through the mouth; that such things as pencils, chewing gum, apples, cups, spoons and forks, passing from the mouth of one individual to the mouth of another, is liable to carry disease with it even if the person from whose mouth it comes appears to be perfectly healthy, for it is a fact that we frequently have germs of disease in the mouth and yet have sufficient power of resistance to these germs so that we ourselves are not diseased but the person to whom the germs are passed may lack that resistance and contract the disease. This has been more than amply demonstrated by investigations in regard to diphtheria, but it is equally true of other diseases. We would have them taught personal cleanliness, the necessity of frequently washing the hands and cleansing the teeth. We would have this teaching given as a part of general hygiene, avoiding unnecessary use of the word "tuberculosis." We would have them taught the necessity of proper nutrition of the body, that it is not right for a child to go to school having nothing for breakfast but a cup of tea or coffee (in Pittsburg, of 396 boys in one school, 92 came without a breakfast), and we would have, as Boston is doing in all of its schools, and Providence in part of its schools, some nourishment given to school children at recess time. The proper time to teach these things is during childhood. We cannot possibly teach them to the present generation of adults, and more especially as a large percentage of the parents sending children to our public schools are of foreign birth, themselves ignorant and not speaking the English language. We would have the older girls of the grammar schools taught cooking and something of food values and of what we should eat to maintain healthy bodies. In other words, we would teach the next generation, while they are still children and we have a chance to, the essentials of hygiene and right living, as well as mathematics and English and an appreciation of the beautiful.

The fresh-air school in Providence is run by the city as one of its regular schools, and a dollar a day is allowed for lunches. The pupils are selected by the League for the Suppression of Tuberculosis, and the extras, such as sitting-out bags, car tickets for those who live at a long distance, etc., are furnished by the League, and the home instruction is given by the tuberculosis nurses. The school had its origin because of the need of such a school for children who had been cared for during the summer in a day camp conducted by Drs. Ellen A. Stone and Mary S. Packard. The suggestion for the school, however, came in part from a paper read by Dr. John A. Lowman, of Cleveland, Ohio, at a meeting of the National Association for the Study and Prevention of Tuberculosis. Such schools have now been started in various places and Providence will soon have additional fresh-air schools. The work is growing rapidly and whatever is said or done it is bound to grow, as all good things grow in our growing civilization. We are pleased with the result of our experiment and feel as sure of the ultimate growth of the movement as did the Old Hen in Rostand's "Chantecler," when to his query, "Have I grown up?" she replied,

"Be it soon or be it late,
Tadpoles must come to frog's estate."

## THE CARE AND MANAGEMENT OF THE TABETIC BLADDER. III. PROGNOSIS AND TREATMENT.

BY J. DELLINGER BARNEY, M.D., BOSTON,
*Assistant Surgeon to the Genito-Urinary Out-Patient Department, Massachusetts General Hospital.*
(From the Genito-Urinary Out-Patient Department, Massachusetts General Hospital.)

THE writer wishes first to discuss the prognosis of tabes as influenced by lesions of the urinary organs; second, to describe the methods and results of treatment of the bladder symptoms.

It was shown in my first paper that urinary disturbances occurred in 90% of cases of tabes dorsalis. It was also found that in 70% of cases there was residual urine and that in 50% of patients the urine was infected, and cystitis was established.

We know that residual urine resulting from any cause will eventually become infected, usually with bacilli of the colon group, and that under these circumstances a renal infection finally occurs. It need not concern us here whether this is secondary to a bladder infection or whether the bacterial invasion is primarily renal and descends to the bladder. The point is that the kidneys become infected.

Most authorities agree that tabes dorsalis *per se* is rarely fatal. Death is usually the result of some intercurrent disease. Of these diseases, those of the urinary system are among the most frequent.

Gowers says, "Kidney complications are the most common; they often develop insidiously and only manifest themselves when life is in peril. . . ."

Oppenheim's opinion is: "If ataxia and disturbances of the bladder develop early . . . a short course is to be expected. . . . In the last

stages the patient dies quickly of cystitis and pyelonephritis."

Somewhat similar is the statement of Sachs: "The prognosis is most unfavorable in those cases in which the early occurrence of vesical symptoms has led to a cystitis or a pyelonephritis. . . ."

To demonstrate this fact to my own satisfaction I have collected the autopsy protocols of 28 cases of disease of the spinal cord in which there was a degeneration of the posterior columns, the pyramidal tracts, or both. In 20 a definite clinical or anatomical diagnosis of tabes dorsalis was made.[1]

In 16 of the 28 cases (57%) grave lesions of the bladder, ureter, and kidney were found. In the absence of definite statements of the exact cause of death, I cannot say positively that it was due directly to disease of the urinary system, but there is no question of the activity or extent of the disease in any case, and in most there was little else to account for death. The lesions noted were cystitis, ureteritis, pyelitis and pyelonephritis. In a few there were renal or vesical calculi or hydronephrosis.

This investigation enables me to share the opinion of other writers as to the importance and gravity of the diseases of the urinary tract in tabes. It also justifies the following conclusion. First, at least 50% of all tabetics having no urinary infection will eventually acquire one; second, in an equally large number death will be due more or less directly to disease of the urinary organs such as pyelonephritis and uremia.

Before continuing, I would make an earnest appeal to the neurologist to procure for us a larger number of autopsies in tabes, and to the pathologist to pay more attention to the lesions of the urinary tract. Post-mortem examinations of tabetics are comparatively rare, even in large institutions where such cases are seen in goodly numbers. I remarked in my last paper that the pathology of the nerve supply of the bladder in tabes dorsalis had never been studied. It may also be said that the urinary organs of these cases receive but little attention from the average pathologist. The foregoing remarks about the importance of these organs would seem to warrant a more detailed and accurate description being accorded them.

## TREATMENT.

The treatment of the cases under consideration must have three objects. First, to postpone as long as possible the onset of urinary infection; second, to reduce such an infection, if already established, to its lowest possible state of activity; third, to relieve symptoms.

I showed in my first paper that trabeculation of the bladder was found in patients with no urinary symptoms whatever, and that it was a sign of increased effort on the part of the detrusor. It was also seen that the compensatory power of the bladder eventually fails, and that residual urine results. This stagnant pool of urine invites infection, and from this time on the life of the tabetic is in danger.

No matter what his condition, he should be given at once one of the many urinary antiseptics, preferably those whose decomposition results in the liberation of formalin in the urine. The usual dose is gr. v, three times a day, but this can be increased to gr. x or xv, if desired. This drug must be taken without remission, in the absence of contra-indications, *as long as the patient lives.* I cannot emphasize this point too strongly. Although these antiseptics may not actually kill the bacteria already in the body, they at least render them less active.

Let us consider now a case of tabes, with a clean urine, and in whom we can find no urinary symptoms whatever. After two or three days of this treatment the bladder should be explored. In the presence of a urinary antiseptic, and with careful asepsis, this can be done without fear of contaminating the urine. The patient should be asked to micturate, preferably with a full bladder, in order to empty that viscus as completely as possible. The urine should be carefully analyzed. He should then be catheterized, preferably with a medium-sized, soft rubber catheter, and if residual urine is found, its amount should be measured. Before removing the catheter, the bladder should be filled with a solution of boric acid, or potassium permanganate, as a precaution against infection. In the absence of residual urine we know that the compensation of the bladder is still unbroken.

The question of cystoscopy now comes up. While not advisable or necessary in every case, there are few if any contra-indications to it, and we have seen that it may be the means of establishing or confirming a diagnosis. It shows the exact condition of the bladder and ureters, and the information thus gained may be of great importance. We also saw that, owing to the anesthesia of the posterior urethra and bladder neck, cystoscopy is a painless procedure. Therefore I do not hesitate to say that in the large majority of cases it can be done without injury to the patient, and without fear of infecting his bladder. Böhme likewise insists on the harmlessness and value of a complete investigation of the genito-urinary tract.

In the absence of trabeculation and residual urine, the patient must continue with the use of his urinary antiseptic, reporting once or twice a month for observation. Sooner or later his attention, or that of his physician, will be directed to his bladder, and any changes in that organ should be taken in hand at once.

If the urine is clean and the catheter shows a residual, more active treatment must be begun. The patient is to be seen once or twice a week. Each time the residual urine is drawn off and measured, and the bladder irrigated with one of the mild antiseptic solutions mentioned above. The value of regular, routine treatment is strongly

[1] These cases were collected, one from the Massachusetts General Hospital; fourteen from the Long Island Hospital, Boston, to whose superintendent I am grateful for his courtesy; thirteen from the Danvers State Hospital, Hathorne, Mass., whose pathologist, Dr. H. M. Adler, I wish to thank sincerely for his painstaking search of the records.

emphasized by Gowers, Sachs and Squier, and it has been demonstrated by my own experience. Its effect is threefold. It gives a brief respite to the work of the detrusor muscle, and by this the amount of residual urine is often considerably reduced; it removes, for the time being, the stagnant urine from the bas-fond; and, finally, it replaces this by an antiseptic solution, of which the effect is to lessen the chances of bacterial invasion, chiefly by reducing the congestion of the bladder mucosa.

As evidence of the beneficial results of this simple, routine treatment I will quote from a few of my records.

S. H., Massachusetts General Hospital.

October, 1910. Residual urine, 3 pints. Catheterization, and irrigation of the bladder twice a week.

November, 1910. Residual, 22 oz. "Has not felt so well in ten years."

Residual is now about 15 oz.

A. R., Massachusetts General Hospital.

March, 1910. Residual, 1 oz. After being catheterized and washed out a few times no residual urine could be obtained.

O'C., Massachusetts General Hospital.

May, 1909. Residual, 14 oz. at first. After a few days it was only ½ oz.

E. F. H., Private case.

April, 1910. Residual, 12 oz. Catherized and washed. At the next visit the residual was reduced to 6 oz.

It is fair to say that the residual may vary considerably from time to time. After a series of sittings, when the amount is less each time than at the previous visit, it may suddenly be found to be greater than when treatment was first started. Then it slowly decreases, finally reaching its former low mark. This is one of the vagaries of tabes of which I can offer no explanation.

Another important feature of what we may call this "prophylactic treatment" is to instruct the patient to urinate at regular intervals throughout the day, *whether he has the desire to do so or not.* I tell him to pass his water on arising in the morning, at twelve o'clock, at six o'clock, and, again, before he goes to bed at night. Other writers have also laid stress on this.

If the urine is already infected, the treatment is similar, but more vigorous. In such cases the dose of the urinary antiseptic may be increased to gr. x or xv, three times a day. The bladder is emptied and washed regularly as before, but more frequently. It must be done at least twice, preferably three times a week, or even oftener, if the conditions warrant it. Irrigation should be done, not with boric acid, or potassium permanganate, but with the more efficient silver nitrate solution (1-5000). The effect of this on a cloudy, ill-smelling urine, is very marked. In many cases it clears up at once and becomes perfectly clear. In others, a urine opaque and foul at the start gradually improves to such an extent that the odor is no longer offensive, and it shows only a slight haze.

The following notes will illustrate these points.

Massachusetts General Hospital, Out-Patient Department No. 137528.

October, 1909. Urine foul, very cloudy, alkaline, residual 10 oz. Bladder washed twice a week with silver nitrate solution. Residual, 6 oz. Urine much clearer, better control. At the present time the residual is 16 oz., urine perfectly clear and clean.

Massachusetts General Hospital, Out-Patient Department No. 111346.

March, 1910. Urine cloudy, acid, strong odor (colon infection). Bladder washed with silver nitrate. "Hasn't passed his urine so freely for over a year." No incontinence now. After a week or two of this treatment, the urine became clear and sparkling; no residual.

S. H., Massachusetts General Hospital.

November, 1910. Residual, 3 pints. Urine like milk. Bladder washed with silver nitrate twice a week. Twenty-two ounces residual, urine much clearer. At the time of this writing, the urine shows only a slight turbidity, and the patient says he has not felt so well in years.

Massachusetts General Hospital, Out-Patient Department No. 111247.

October, 1909. Urine foul, cloudy, contains much pus, B. coli present. Residual, 3 or 4 oz. for some months. Daily treatment.

In February, 1910, the residual varied from 1 to 3 oz., the urine was no longer foul, and only slightly cloudy.

I might cite other cases in whom this treatment had wrought much improvement. By the reduction of the amount of residual, and by the improvement of the condition of the urine, hence also of the bladder itself, many patients had better control (broadly speaking) of their urinary apparatus than they had had for a long time. Nocturnal incontinence, urgent urination, and even retention were sometimes entirely done away with, after one catheterization and washing of the bladder. In most patients this improvement continued as long as they were under observation.

I now propose to show that the varied and annoying bladder symptoms, due perhaps quite as much to the inco-ordination of the muscles of micturition as to bladder infection, may be greatly influenced by still another form of treatment. I refer to the re-education of the muscles concerned in urination. It is well known that by what are called the "Fraenkel exercises," the muscles of locomotion can be re-educated up to a remarkable degree of efficiency. Those of the bladder are quite as amenable.

The writer claims no originality for this. Its value was shown him in a most convincing and entertaining way by the late Dr. Samuel Alexander, of New York, at his clinic in the Bellevue Hospital. His cases were mostly post-operative, but the principle is the same, and I have satisfied myself that it is as applicable to tabetics as to those with incontinence following prostatectomy.

The following statement, by Williams, explains briefly and clearly how the results of the re-education of muscle is brought about.

"The return of functional capacity, acquired by what is known as the Fraenkel exercises, is not due to the re-establishment of old nerve paths, or the establishment of new channels of afferent

information, as is so often supposed; but it is due to the patient learning volitionally to utilize the imperfect afferent information which is all that remains to him, and to create from it a new set of automatisms, to replace those which now functionate in so disorderly a fashion."

Let us now take a typical case of tabes with bladder symptoms. He has difficulty in starting the stream, the desire to urinate is infrequent, the urine trickles from the meatus like molasses from a jug, occasionally he wets the bed, or when he coughs he is annoyed by a little gush of urine into his trousers. One can readily appreciate the wretchedness and suffering of such an individual.

The confidence and attention of the patient must first be gained. Let him see that you want to help him, that he can help himself greatly by co-operating with you, and assure him that the future offers hope. Impress it upon him that he must obey you absolutely. All this is easily brought about if undertaken in the right way, but both patient and physician must be prepared to spend much time and great patience before any permanent change occurs. Empty and wash his bladder as usual. Fill it to its capacity with a 1-5000 solution of silver nitrate. There may be a tendency to incontinence at this point, but order the patient to retain it. He generally does so, or will, after a little practice. Now have him retain the fluid, as best he can, for perhaps a quarter of an hour, increasing this period at each visit. Meanwhile have him practice this at home by retaining the urine for a time before each micturition. The improvement caused by this simple procedure is often amazing. A little later, when complete control has been gained, more complicated gymnastics are employed. After filling the bladder, tell the patient to micturate. Then, without warning, order him to check the stream. Now tell him to begin once more to empty the bladder. Continue in this way, starting and stopping at irregular intervals, until the bladder is empty. I usually repeat the performance by filling the bladder a second time.

At first, your order, either to start or stop the stream, will meet with little or no response. But, after sometimes a surprisingly few days of effort, the patient is able to obey with alacrity. He has learned to concentrate his whole attention on the act of micturition, even as he does on his locomotion when taught to do so. He awaits your order with his whole mind on the subject, and, when you tell him to stop urinating, he contracts his sphincters and perineal muscles, sometimes with visible effort, and the order is executed. The more he improves, the more encouraged he becomes, and the more he tries to do what you tell him. It becomes his pride to show you how athletic he really is, and how beautifully his muscles work, even as the small boy displays his ability to run or jump. He takes real pleasure in demonstrating his ability to hit the opposite side of the basin with the stream from his bladder, a great contrast to the drooling urination which annoyed him at first. He coughs violently and frequently, yet not a drop leaves his bladder. He shows you his dry underclothing. For these and many other newly acquired comforts he shows prompt and ample appreciation.

To cite a concrete example of what can be accomplished by these bladder exercises, I will give a résumé of the following case. It was one of the worst I have ever seen.

Massachusetts General Hospital, Out-Patient Department No. 111247.

Male, age sixty-five years. Came to the Genito-Urinary Out-Patient Department in the latter part of January, 1910.

Three months previously he began to have frequency of micturition and incontinence. Urination about every five minutes, no normal sensation. Only a small amount passed each time. Stream small, and of low pressure. Considerable dysuria. At night his urine leaked constantly, requiring the use of a urinal, which he also wore in the daytime.

Urine very cloudy, strong odor, acid, trace of albumen. Sediment contained much pus, no casts seen. Culture shows pure growth of bacilli of the colon group. Residual, 4 oz. Owing to the severe cystitis, the bladder was much contracted, holding only about 5 oz.; hence the incontinence was essentially the overflow from a full bladder.

The patient came to the hospital every day, his bladder being emptied and washed each time with silver nitrate solution. He was given urotropin, gr. x, three times a day. Muscle training was begun at once with daily practice. This continued until March, 1910, and then twice a week until June, 1910. Improvement was slow, but generally steady; on some days, however, the patient seemed to have lost all that was gained. At first the stream trickled from the meatus; it could not be started or stopped at will, and incontinence was essentially complete. There was much scalding with urination.

After a month or six weeks the residual was reduced to an ounce (occasionally it would be 2 or 3 oz), the urine was only slightly turbid, there was no dysuria. The stream could be ejected for a distance of several feet, control was so good that my orders to start or stop it could be obeyed at once. The frequency subsided, so that the patient not only went for as long as two hours, day and night, without urinating, but also felt the desire to urinate, and could control it until he reached a toilet. Finally, he abandoned his urinal at my advice, and went about "dry shod." The bladder capacity was now always 5, generally 6 oz., partly on account of the improvement of the cystitis, partly on account of the stretching to which I subjected it by gently forcing in the fluid.

Some one has said that "you can't make a silk purse out of a sow's ear." I do not claim that this feat can be performed even now. But there is no question that the cases under consideration can be put on the road to comfort, and that the ultimate mortality from diseases of the urinary system can be greatly reduced. I might also add that the treatment mapped out by the neurologist, and that just described in no way interfere with one another. On the contrary, the combination of the two is to be regarded as absolutely essential to the welfare of the tabetic.

The conclusions to be drawn from this investigation are,

1. Infection of the urinary tract occurs in over 50% of patients with tabes dorsalis.

2. The mortality from such an infection is nearly 60%.

3. Catheterization and irrigation of the bladder, at regular and frequent intervals, combined with the constant use of an efficient urinary antiseptic will (*a*) delay, prevent or reduce the activity of urinary infection; (*b*) postpone the appearance of residual urine, or diminish its amount if present; (*c*) relieve symptoms.

4. Re-education of the muscles of micturition, combined with local treatment, will cure or relieve most of the symptoms which harass the life of the tabetic. It is, therefore, of the utmost importance.

5. The combined treatment of the nervous system and of the urinary tract is essential for the welfare of the patient.

## Medical Progress.

### REPORT ON PEDIATRICS.

BY THOMAS MORGAN ROTCH, M.D., AND CHARLES HUNTER DUNN, M.D.

#### RECENT RESEARCHES IN DIGESTION, NUTRITION AND FEEDING.

An interesting paper, by Meara,[1] in the *Archives of Pediatrics*, summarizes and reviews some of the recent advances made in the subjects of the infantile digestion, nutrition and feeding. He gives a review of the known facts about the process of normal digestion, in the light of the most recent investigations, pointing out particularly that the old view of the large part played by incomplete development in young infants can, in the light of the most recent researches, no longer be held. A review of the researches of Czerny and Keller,[2] Uffenheimer[3] and Tobler[4] shows that all the digestive ferments present in the adult have been found in the young infant, so that the identity of the digestive function in infancy and adult life, in so far as the ferments and chemical nature of the products found are concerned, is established.

We believe that at present it would be going too far to regard the processes of digestion in infancy and adult life as identical on this evidence, or to conclude that imperfect development plays no part in the disturbances of function seen in infancy. No evidence is offered showing that the function in infancy is not more easily disturbed by slight causes, or that such disturbances are not partly due to underdeveloped function.

Meara mentions a distinction which, in the light of a number of recent researches upon the bacteriology of the intestine, is assuming great importance, namely, between the processes of fermentation and putrefaction, although he does not clearly explain this difference, and appears to minimize the rôle of bacteria as compared with the rôle of improper chemistry of the food.

He reviews some interesting work of Schwartz[5] on the differences between human milk and cow's milk in respect to the emulsification of the fats. Schwartz found that the fat globules are surrounded by a zone of clearer substance, which he calls periglobular substance, of which the elasticity varies in cow's milk and human milk. It is much less in cow's milk, causing the fat very easily to go out of emulsion, from slight causes, such as even the act of sucking. It may be increased by heating, which may account for the easier handling of such milk by some infants.

Alexander and Bullowa,[6] in recent studies on the protective action of colloids in milk, have shown that some colloids are insensitive to electrolytes and are capable of dissolving again after desiccation. Others are readily coagulated by electrolytes, but cannot be redissolved after desiccation. The former are called reversible, the latter irreversible, colloids. The reversible colloids possess the property of protecting the irreversible colloids from coagulation, and permit them to redissolve after dessication, and reversible colloids acting in this way are called protecting colloids. In milk, casein is an irreversible, coagulating colloid, and lactalbumen a reversible, protecting colloid. The authors believe this protecting action throws a strong light on the differences in coagulation of cow's milk, with its larger ratio of casein to lactalbumen, and human milk with its smaller ratio. This protection prevents the curds from becoming tough and leathery in the stomach, and it may be increased by the addition of certain substances, among which is sodium citrate, the action of which in increasing the digestibility of milk may possibly be explained through its action as a protecting colloid.

Meara takes up the various food elements in turn, reviewing certain recent publications having a bearing on the problem of nutrition. He quotes Orgler[7] to show that differences in the chemistry of the casein in human milk and cow's milk have yet to be demonstrated. In support of the view that the infant is as well able to handle the excessive casein of cow's milk as the smaller amount found in human milk, he mentions Langstein's[8] work, demonstrating that the stomach contents of infants show about the same amounts of peptones and albumoses after cow's milk and after woman's milk; also Orgler, who found, in both instances, the same amount of nitrogen in the stools.

The work of Meyer,[9] who caused children to thrive on human whey plus cow's casein and fat, while they failed to thrive on cow's whey plus human casein and fat, is brought forward as additional evidence that casein cannot be the injurious factor in artificial feeding.

We believe that this evidence does not justify any such conclusions as to the casein and that the fallacy can be seen in the use of the words "the njurious factor." It is to the idea that there is

*an* injurious factor, one factor more important than others, that most of the faulty conclusions in modern infant feeding can be traced, as well as to the idea that facts demonstrated as true of some infants are true of infants in general. These researches merely prove that some infants can digest and absorb the casein of cow's milk as well or better than that of human milk, but do not prove that this is true of all infants, or that the contrary may not be true of some.

The harmless character of casein has been further supported by certain recent studies on the curds found in the stools of infants, many of which studies show that the curds are due to other substances. This question of the composition of the so-called casein curds is still a subject of discussion upon which opposite views are held, although recent work has thrown considerable light on the subject. It has been definitely proved that the curds are not exclusively due to casein, and a recently published study by Meyer and Leopold [9] have shown they may be composed of fats, fatty acids, bacteria and epithelium. This does not, however, prove they are always due to these substances, or that they are never due to casein. The results of careful studies by Talbot [10] on this subject show that they may be due *either* to the above-mentioned substances or to casein. He found that, while the small curds are composed mainly of fat, mostly in the form of fatty acids and soap, the larger curds are, in fact, composed of some proteid, probably casein or one of its derivatives, which, on coagulating, entangles the milk fat into its meshes. The demonstration that the curds are not always casein is a valuable addition to our knowledge, but it does not prove that casein cannot be an injurious factor in artificial feeding nor that casein can rightly be looked upon as the most innocent and easily handled of the food constituents.

Meara discusses the function of the proteid in supplying nitrogen for the repair of waste, for growth and for furnishing heat and energy. In this connection nothing very new is brought out. He emphasizes the well-known importance in artificial feeding of arranging the food so as to spare the nitrogen for storage.

In speaking of the proteids, he not only takes the view that no harm is to be apprehended from difficulty of digesting the casein, but entirely neglects the rôle of the proteids under the influence of bacteria in the intestine. The subjects of fermentation and putrefaction are wholly ignored in connection with the proteids.

In regard to the fat, the differences in the fats of human and cow's milk, both the physical differences in the emulsion brought out in the work of Schwartz, and of Meyer and Leopold, and the chemical differences, such as the higher contents of oleic acid and other acids, are discussed. Meara's conclusions, that in view of these differences our efforts at dealing with fat intolerance by making quantitative changes only are crude, are certainly justified. Unfortunately, the progress of our knowledge has as yet given us no better method.

A large part of Meara's paper is devoted to the elaboration of a practical method of feeding based on the aspects of the problem of nutrition discussed. Briefly, the basis of this method is the assumption that metabolism experiments have established a definite protein need, expressed in per cent of the caloric needs. Taking approximate caloric needs as having been established by the energy quotient of Heubner, he so distributes his fats, proteids and carbohydrates, and so arranges his quantities and intervals, as to fulfill the protein requirements with as little burden on digestion as possible. As a result, he believes that the use of cow's milk may be reduced to a simplicity, that the use of creams is unnecessary and that the majority of infants may be successfully fed on dilutions of whole milk without the aid of creams. He gives a summary of the uses of dilution of whole milk in the Breslau clinic.

We do not at all agree with Meara's conclusions in this respect. In the first place, we do not believe that the caloric and protein requirements of infants of different ages have been established to an extent sufficiently definite to permit of such universal application in practical feeding. The data as to the protein and caloric needs of children are not very extensive. The valuable observations of Camerer [11] were based on the study of his own children only. Czerny and Keller [2] have collected and analyzed all the results on this subject up to 1906, and the literature on the subject has been recently summarized by Selter.[12] In the first place, the figures of the various observers show wide variations. More significant, however, is the fact that the figures in most cases are deduced by taking averages of the results of a series of experiments. We believe that many of the difficulties encountered in our efforts to apply the results of the scientific researches of continental investigators to practical infant feeding may be traced to this method of using averages. Such a method presupposes that the answer to the problem is represented by a fairly constant figure and that to find this figure is the only task of the investigator. This assumption of a fair degree of constancy may be applicable to laboratory investigations but is not applicable to investigations on living infants, in which it is absolutely unwarranted. It is quite possible to conceive that a series of researches upon living infants might give an average which was nowhere near the truth for any one infant in the series, because an average may be obtained from a series of cases in which each case represented an extreme on one side or the other. We believe that the available evidence from living infants goes to show that protein and caloric requirements are so modified by individual variations, and by other factors, such as varying power of digestion and assimilation, that extremes are the rule rather than the exception.

Two methods may be employed in estimating the protein and caloric requirements. In the first method, infants are fed on various arbitrarily chosen foods, of calculated protein and caloric values, and the results noted; in the second

method each infant is fed on a food adjusted experimentally, by careful percentage modifications, until the best results are obtained for the individual child. Then the calories and protein ingested are calculated. It is the first of these methods which has been mainly used in the studies of caloric and protein requirements. We believe the second method, which takes into account the factor of individual variation, is better adapted to give an idea as to how far caloric and protein requirements may be employed in practical infant feeding. There has been little work done by this second method. Ladd [13] employed it in a study of twenty artificially fed babies. Some of his conclusions are as follows: "The average energy quotient required in each quarter of the year varied so widely from the extreme low and extreme high quotients, and bore so little relation to the rate of growth, that one may seriously and with reason doubt the value of making it the basis by which to calculate the infant's food requirements. . . . The caloric value of the food, expressed either in terms of the number of calories ingested daily or as the energy quotient, is not the most important consideration in determining the quality of an infant's food. The nutrition of an infant depends primarily on its power to digest and assimilate milk. These functions are best served by modifying the percentages of the constituents of milk so as to adapt the food to the individual needs of the infant."

While caloric needs cannot be too rigidly and universally applied as a basis for proper artificial feeding, we believe that an appreciation of approximate caloric requirements should be used to serve, not as a basis, but as a guide and control, in intelligent feeding. When used in this way, as a control, it is frequently of service in answering some of the questions presented by a particular feeding problem and will prevent wide and obviously harmful deviations. Our estimation of the caloric value of the food given should be made in all difficult cases.

The method of feeding outlined in Meara's paper is further based on the results of researches on the problem of nutrition outlined in the first part of his paper. We believe that the objection to the method lies in the assumption that researches carried on with a certain number of infants are true of infants in general. This assumption is the basis of a host of so-called methods, or simplified methods, of feeding, each one of which is based upon certain facts established by a particular research.

From the earliest times there has been a tendency in infant feeding to regard each addition to our knowledge as a fact of transcendent value in the solution of the problem of nutrition, capable of a wide application; the result has been a series of methods in which may be traced the successive steps through which the sum of our present knowledge has been attained. We believe that each of these steps should be regarded as a single addition to our knowledge, applicable only to certain infants, and that our feeding should be based on the sum of our knowledge. At present the sum of our knowledge points to individual variation as the most important factor in the problem, to meet which we can use no single method, but require a multiplicity of resources, among which every addition to our knowledge should be reckoned as one, providing us with one weapon to be used in certain individual cases.

One point brought out by Meara appears to us to be of great value in practical artificial feeding, namely, the question of the amounts to be given at a feeding. The amounts given in most textbooks are based on anatomical measurements of gastric capacity. They do not represent the physiological capacity, that is, the amount which an infant may properly take at a single feeding, which is considerably greater than the amounts based on anatomical measurements. The question of physiological capacity has been discussed recently in an article by Mosenthal.[14] His tables are derived from Pfaundler and Camerer. Rotch,[19] as early as 1893, pointed out that the physiological capacity differed from the anatomical, and gave tables showing both. The comparison between the figures for anatomical and physiological capacity given in Rotch's textbook, compared with those for physiological capacity given by Mosenthal, is shown in the following table:

| | Physiological. | | Anatomical. |
|---|---|---|---|
| | Rotch. | Mosenthal. | Rotch. |
| First month, | 70.5 ccm. | 105 ccm. | 75 ccm. |
| Second month, | 96.6 ccm. | 125 ccm. | 105 ccm. |
| Third month, | 118.8 ccm. | 145 ccm. | 120 ccm. |
| Fourth month, | 137 ccm. | 145 ccm. | 135 ccm. |
| Fifth month, | 158.4 ccm. | 170 ccm. | 165 ccm. |

It will appear that the figures given by Mosenthal for physiological capacity are much larger than those of Rotch. This can probably be explained on the ground that the babies on which Mosenthal's figures (quoted from Pfaundler and Camerer) were based were given all the milk they would take, and could handle, whereas Rotch's figures are based on babies who were thriving on measured amounts without showing signs of hunger. The reason for the physiological capacity being greater than the anatomical is explained by the recent work on the digestion of milk. It has been shown that coagulation begins at once, and that the milk is separated during the meal into solid and fluid portions. The passage of the fluid portion into the the duodenum begins at once.

Meara believes that the physiological capacity should be used as the basis on which to determine the amounts to be given at a feeding. Here again we cannot agree with Meara as to the advisability of a general application of any such rule. Babies will frequently, under various circumstances, such as a lessening of the digestion power from some outside cause, take more milk than they can properly handle. Again, the figures, being based on averages, are not suited to indiscriminate application to individuals. It is probable that in this respect also the factor of individual

variation plays the most important part in the feeding problem, and that babies cannot successfully be treated as a class, but must be treated as individuals. The exact amounts and intervals of feeding can only be determined by practical experience and must be fitted to the particular patient. Experimental work on anatomical and physiological capacity can only furnish us with approximate guides, serving as controls, to enable us to avoid dangerous extremes. It is probable that the anatomical capacity should be considered as the minimum, and physiological capacity as a maximun. Experience has shown that in feeding it is safer to begin with minimum figures and to increase only when increase is indicated in the individual case.

One of the most recent and significant additions to the literature of the subject of nutrition is found in the publications of Finkelstein.[15] The basis of his work is the idea of a unity of a multitude of disturbances of nutrition, which idea was originally due to the work of Czerny and Keller, but which Finkelstein worked out in detail in his clinic in Berlin. He attributes the greatest variety of disturbances to "food injury," which so weakens the functions of nutrition that a diminution for the tolerance for food is produced. He divides this disturbance of nutrition into four stages. The first stage he calls a disturbance of balance (Bilanzstörung) which is characterized clinically by a failure to respond to an increase in the quantity or quality of food; this failure to respond he calls the "paradoxical reaction." The children fail to gain on a food which they appear to digest well. He attributes this disturbance to the fat in the food, regarding the proteid as absolutely innocent.

In the second stage, the resistance to bacterial action is lowered, fermentation processes begin, with a reaction of the mucous membrane, and local symptoms appear. This disturbance is regarded as primarily due to fat, but it may be due to excessive carbohydrate or to varying tolerance to different carbohydrates.

The third stage is called that of alimentary decomposition, characterized by steady diminution of the powers of assimilation and progressive loss of weight. This stage is regarded as due entirely to the food injury, the fats and carbohydrates being responsible. These food substances are regarded as withdrawing from the body some important biologic substance necessary for proper assimilation. The old ideas of the rôle of bacteria in producing fermentation, decomposition or infection of the tissues is largely disregarded. There is intolerance of fat and increasing intolerance of sugar. Only human milk, in extreme cases, can relieve this stage, though in the milder cases a gain may be obtained by careful cutting down of the food.

The fourth stage, that of alimentary intoxication, may develop during any stage, or without previous symptoms, its first manifestation being a rise of temperature. Among its symptoms are diarrhea, loss of weight, fever and disturbances of the nervous system. The intoxication is regarded as coming from the food, sugar being always the factor causing fever. The fat contributes to the sugar intoxication, by intensifying decomposition, and thus increases the susceptibility to intoxication by sugar. Decomposition is not regarded as due to the absorption of injurious substances, but rather to the withdrawal of certain constituents from the tissues. Intoxication is due to a foreign substance, sugar, circulating in the blood. Sugar may produce fermentation only, fermentation and decomposition, or fermentation and intoxication.

Just how and why the fat and sugar bring about these nutritional disturbances is the chief subject of research by many continental and some American investigators. Meyer,[16] reviewing our knowledge of the rôle of the salts in metabolism, believes that it is through the salts that the fat and sugar exert their injurious influences. The fats, in forming soap stools, and the carbohydrates, in forming fatty acids, divert the salts and thus rob the tissues, the salts being very important in metabolism.

These views of Finkelstein and his school are so new, and so widely in opposition to previously accepted views, as to appear revolutionary. It is quite impossible at this time to express an opinion as to what will be their final value, or their bearing upon the problem of practical infant feeding. We believe that in all probability they will be found to represent facts of value as an aspect of the problem of nutrition. Their fault will come, as usually happens, from too general application, without sufficient reckoning of the factor of individual variation. Already the authors of these views have applied them in a method of infant feeding which involves a highly artificial elaborately prepared infant food containing a high amount of casein, a minimal amount of carbohydrates, a variable amount of fat and a diminished amount of salts called "*Eiweissmilch*." We have already pointed out the fallacy of this method of applying the results of scientific research. The danger comes from taking truths which are parts or aspects of the whole, and using them as truths of especial or transcendent value. We have had brought forward successively as the chief cause of disturbances of nutrition, first, the casein, then the fats, and now finally the carbohydrates and the salts. Even the whey proteids have by no means escaped blame. Each advance has been considered as of sufficient value to warrant a new method of feeding, instead of only of sufficient value to supply us with one new weapon.

We cannot believe, for instance, that food injuries are the whole cause of nutritional disturbance. It has been repeatedly shown that the great prevalence of such disturbances in the summer months cannot properly be attributed to food injuries, but that other factors enter in, such as impaired power of digestion from external influences, and bacteria. These factors are entirely neglected in the views of Finkelstein and his school. That loss of weight is chiefly due to withdrawal of a biologic substance from the body, instead of to insufficient

absorption, or to poisoning by bacterial products, is far too revolutionary for complete acceptance. That intoxication is due to sugar circulating in the blood, instead of to the products of putrefactive organisms, will take long to establish.

As to the reported results of feeding with *Eiweissmilch*, we can only point out that, in the history of infancy feeding, good results have been reported from each new method, and always will be reported, because the factor of individual variation will always make such results possible.

Before closing this discussion of the subject of recent advances in the problem of feeding and nutrition, we must call attention to an article by Kendall,[17] which brings out certain features of the other aspects of the problem. Kendall discusses the rôle of lactic acid bacilli in intestinal disturbances, giving a very complete summary of the most recent views on this subject. He points out that the purpose of giving living cultures of lactic acid bacilli, as elaborated by Metchnikoff, is to restrain the activity of proteolytic (or putrefactive) bacteria in the intestinal tract. The proteolytic bacteria act upon protein and protein decomposition products, forming aromatic substances which act as poisons to the host. There are two distinct types of bacterial activity in the intestine, to differentiate which the recent distinction between fermentation and putrefaction has been made. It is the proteolytic or putrefactive bacteria whose products have been shown to be capable of producing harmful intoxication.

There are three types of bacteria, of which the exclusively putrefactive, such as the proteolytic bacteria, are one, and the exclusively fermentative, such as the types of lactic acid bacilli, are a second. The third type is by far the largest and includes many of the best known of the intestinal flora, the bacillus coli being a familiar example. This third type is called facultative, because the organisms develop well in proteid media, and also in media mainly carbohydrate, with only a small amount of protein. In the former case their products are typical of putrefaction, in the latter of fermentation, and they, therefore, combine the attributes of both varieties of organism. This has been shown by laboratory experiment. The addition of carbohydrate to the culture media will change the process from the putrefactive type to the fermentative. In the intestine, the addition of carbohydrate not only changes the facultative organisms from putrefactive to fermentative development, but has been found to cause a decrease both in the numbers and the vitality of the obligate proteolytic organisms, accompanied by a corresponding increase in the normal intestinal fermentative organisms.

The object of giving living cultures of lactic acid bacilli is to further restrain proteolytic activity through the liberation of lactic acid in the midst of the developing putrefactive organisms.

Kendall points out that the bacillus Bulgaricus, which is largely used in lactic acid therapy, is found to localize itself chiefly in the small intestine, whereas the bacillus acidophilus, another strain, and the most thoroughly studied of the intestinal lactic acid bacilli, is found in the large intestine. If the accepted idea that the seat of bacterial activity upon protein is in the large intestine is true, the acidophilus should be used rather than the Bulgaricus. Kendall believes that there may be very decided bacterial decomposition of protein in the small intestine as well. He demonstrated this in experimental animals. It would seem that both strains of lactic acid bacilli may have their special value.

The cause of objectionable proteolytic activity is an excess of protein in the diet of the host, or any factor causing stasis, or impaired absorption of protein, which conditions stimulate the development of the putrefactive organisms. The restraint of this activity may be brought about by adding to the diet easily fermentable carbohydrate and living lactic acid bacilli, which act in the way described above.

There may exist in young children three types of bacterial activity of an undesirable nature: (1) A true proteolytic, with the formation of putrefactive products. (2) A mixed putrefactive and fermentative, in which proteolytic and facultative organisms act symbiotically, producing much gas and destruction of protein. (3) A true fermentative, in which the overgrowth of lactic acid bacilli is so unrestrained as to cause harm. Salge has shown that in certain of his cases an enteritis resulted when the normal intestinal lactic acid bacillus proliferated to an unusual degree.

The sharp contrast of these views of Metchnikoff and his followers, as summarized by Kendall, and those of Finkelstein and his followers, outlined above, is only an example of the many-sided character of the problem of nutrition and the associated gastro-enteric disorders. We have, on the one hand, the followers of Finkelstein, attributing everything to food injuries, regarding the proteid as absolutely innocent, and the chief source of injury as lying in the fat and carbohydrate. We have, on the other hand, the followers of Metchnikoff, attributing part of the trouble to bacteria, regarding the proteid as chiefly guilty in certain disturbances, and the carbohydrate as the saving element. Each view is supported by experimental evidence and clinical observation. The solution lies in regarding the problem as one of many aspects.

For the clinician, the chief difficulty lies in deciding which aspect of the problem is present in a particular case. What we need most is an increase in our means of determining which of many possibilities is actually present. In this connection, such work as that of Morse and Talbot,[18] in giving us a simple method, easy of clinical application, for estimating intestinal conditions from examination of stools, is very valuable, perhaps more valuable than some of the prolonged, detailed, scientific researches upon limited aspects of the problem. Such researches have provided us with plenty of weapons. What we need is increased means of knowing how to use them intelligently. At present we must know the

various aspects of the problem, and all the multiplicity of resources with which their study has supplied us. We have still comparatively little to guide us in our choice of resources except personal experience, and it is better to proceed by grouping experiments, using all our resources, than by the consideration of any one aspect of the problem which limits our choice.

THIRTY-SECOND ANNUAL MEETING, HELD IN WASHINGTON, D. C., MAY 3, 4, 5, 1910.

JAMES E. LOGAN, M.D., *President.*
JAMES E. NEWCOMB, *Secretary.*

(Concluded from No. 26, p. 998.)

### XVIII. THE CUTTING IN TWO OF A LARGE STEEL PIN, WHILE TRANSFIXED IN THE LEFT BRONCHUS, AND ITS REMOVAL BY LOWER BRONCHOSCOPY. EXHIBITION OF A BRONCHOSCOPIC PIN-CUTTER AND FRAGMENT-HOLDER, DEVISED TO MEET THE EMERGENCY.

By W. E. CASSELBERRY, M.D., Chicago.

It is proposed, as a general principle, in order to facilitate the bronchoscopic extraction of immovably transfixed pointed objects, such as pins, needles and perhaps open safety pins, to first divide them, via the bronchoscopic tube, into two or more parts; and the instrument or pin-cutter devised for the purpose is commended.

A glass-headed, 1½ inch, very sharp, black, steel pin was immovably transfixed in the first bronchial branch and across the left bronchus of a fifteen-year-old girl, where, without causing serious discomfort, it had remained for ten weeks. Freedom from suffering for so long a period naturally leads a patient to forget or doubt the presence of a foreign body, and as the physical signs are indefinite when the object is but slightly obstructive, the x-ray supplemented by bronchoscopic inspection may be the only means of positive demonstration. That the x-ray, however, has its shortcomings and needs to be supplemented by direct observation through the bronchoscopic tube was evidenced by a serious delusion in the interpretation of the first x-ray plate. An extraneous or false shadow, "very like a pin," which appeared on the right side, was accepted for a time as the actual outline, whereas the pin was lodged on the left side, its real shadow being visible, but obscured in the shade of the sixth rib. Furthermore, nothing short of the upper bronchoscopy could have disclosed the exact position and state of transfixion of this pointed object, information which was absolutely essential to devising a plan for its removal.

"How it happened" is worthy of comment in order that women may be warned against a certain habit while gowning. The young woman, with pin in mouth and skirt in hand, in readiness to drop the skirt over her head, raised on high her outstretched arms, — an act which is identical with the first movement in Sylvester's method of artificial respiration, which owes its power to the fact that raising the arms expands the lungs and causes an inrush of air, the mouth opening itself as if by instinct; and, at the some moment, to let the skirt fall clear of her hair, the head was thrown backward and face upward, bringing the mouth, larynx and windpipe into a straight vertical line, — an attitude identical with the sword-swallower's position. The pin, let loose, simply dropped with the air current head foremost into the left main bronchus, and on downward till its head and two thirds of its stem had passed into the first bronchial branch; where, being too long to quite make the turn, it was arrested, with its head compressed against an upturning segment of the bronchial branch and its point against the opposite wall of the main bronchus. Both ends of the pin being against a barrier, the impact of cough sufficed to drive its point firmly into the broncial wall. At the first operation, that of upper bronchoscopy, every effort was made to displace it. The pin was grasped at the depth of eleven inches with various bronchoscopic forceps, the grasp being many times renewed to change forceps or vantage point of the grip, but without avail, except the conviction that it must first be cut in two.

A valid criticism, which suggests itself, is the disposition of the parts of a pin, when cut, to fly asunder, hence, possibly, to drop out of sight or out of reach of the bronchoscopic forceps. But this contingency did not occur, for the beak-shaped, slotted scissor-like cutting mechanism is so devised and elaborated that one of the two fragments will adhere with dependable regularity and firmness in the serrated slit alongside the blade bevel, as long as the blades are not permitted to reopen, and, moreover, the operator can elect the fragment to be so held by turning the blade. Therefore it was planned to minimize the major risk of losing the smaller fragment by electing it to be held in the grasp of the pin-cutter.

It was deemed expedient, by reason of the novelty of the procedure, to operate this time by lower bronchoscopy, although it is now realized that the pin-cutter and the principle of its use are applicable as well at the longer range of upper bronchoscopy. A few additional efforts to extract the pin without cutting having proven futile, the pin-cutter was passed down the bronchoscopic tube. It operated exactly as planned, one could hear the snap, see the larger fragment shiver and then discern the small pointed piece in the beak of the instrument, held fast in which it was withdrawn, and in another minute the larger piece, in the grip of a bronchoscopic forceps, came safely out.

DR. CHEVALIER JACKSON, Pittsburg, referring to Dr. Casselberry's statement in regard to the unreliability

of the x-ray negative, said that all have been deceived by radiographs at times, and a surgeon should declare his right to make an examination anyhow when it seemed required. Dr. Emil Beck has a method of taking radiographs with the aid of bismuth paste which is very useful in locating a foreign body. It requires no great amount of intellect, but an extreme degree of ingenuity to remove a foreign body without injury to the patient, and such cases as this and the one reported the previous week by Dr. Richardson show how ingenuity can overcome almost insurmountable difficulties. He then presented an instrument which he had devised for the purpose of removing a safety pin lodged point up in the esophagus or trachea, which had proved to be especially useful in little patients where the esophagus is to small to allow the introduction of other instruments.

Dr. Coakley, New York, reported a case similar to that presented by Dr. Casselberry, in which after four ineffectual attempts to remove the foreign body, made at intervals of two weeks or so, the patient developed an abscess of the lung and died. If they had had the aid of the instrument shown by Dr. Casselberry, their efforts might have proved successful.

Dr. Halsted, Syracuse, related another similar case. The skiagraph showed the pin in the first division of the right bronchus. A number of granulations had formed around it. By upper bronchoscopy, the shank of the pin was caught with the Jackson forceps, but in withdrawing it some resistance was encountered and the pin was lost. A lower bronchoscopy was then performed and with the alligator forceps the head of the pin was removed, but the shank could not be found, although diligent search was made. There was a good deal of mucus and some vomiting during the operation, and it may have been lost on the floor. At any rate, the child was relieved, the tracheotomy tube was removed in the course of a few days and an uneventful recovery followed. He felt confident that the shank had been removed at the first attempt when the resistance was encountered, but had been unobserved in the vomitus, and was lost. It might just as well have gone into the lung, but the x-ray did not show it.

Dr. Emil Mayer, New York, said that all owed Dr. Casselberry a great deal for devising this ingenious instrument, which not only cuts but grasps, so averting the danger of cutting off a piece of pin and losing it. He then cited a case in which, being unable to see or feel the foreign body, he had refused to make further attempts to remove it. The foreign body had been in so long that granulations had formed around it; it was not producing symptoms, and he felt that it would be harmful to the child's best interests to attempt to remove it. The child is perfectly well, except that it has a tack in its bronchus.

Dr. R. C. Myles, New York, said that the suffering caused by the attempt to dislodge a foreign body from the respiratory tract is often very intense, and cited an amusing case of a Russian patient in which he finally succeeded in removing a long tack after employing various devices and overcoming the variously expressed protestations of the patient.

Dr. Casselberry, closing the discussion, said that, with no thought of self-aggrandizement, but to offset the extreme modesty of Dr. Jackson, he must take exception to his statement that only mechanical ingenuity, not intellect, is required for these cases. Mechanical science, of course, is merely mechanical, but the application of science to these cases, indeed, the application of science in general, is intellectual. It takes intellect to control and retain the patient under circumstances of this sort. The whole time required to examine and make the various efforts to find the pin was four and a half months. To maintain control of your patient for so long a time, and even of your own courage, and to have the force of your own convictions to persevere, — that is intellect.

### XIX. Removal of Malignant Growth of the Larynx, with Specimen and Presentation of Patient.

Charles W. Richardson, M.D.

The patient was a man forty years of age who had suffered from epithelioma of the left vocal cord. The removal of a portion of the growth showed it to be epithelioma, and immediate preparation was made for operation. The operation was a thyrotomy without tracheotomy. The subsequent steps in the operation were the subperichondrial separation of the growth from the wing of the thyroid cartilage, and then the removal of the mass in its entirety beyond the line of safety by scissors. Healing took place rapidly, convalescence being perfect, and the patient is now living, thirteen months after the operation, without recurrence, and with an excellent voice.

Dr. Solis Cohen, Philadelphia, said that it gave him much pleasure to hear these papers. A number of years since he had removed a case of obstructive growth of the larynx by the subperichondrial method, which was original with himself. The perichondrium is pulled off to a certain distance beyond the growth, then everything is taken up together and cut. The growth is not touched at all, and there is no possibility of conveying anything into the healthy portion of the body with a knife with which a tumor has been cut. It is five years since this patient was operated upon and he is still alive.

Dr. Ballenger, Chicago, reported a case on which he had performed this operation a year ago for epithelioma of the larynx. Two months ago, the patient, a man sixty years of age, wrote that he was in good health and there were no signs of recurrence.

Dr. T. P. Berens, New York, said that during the previous week he had reported before another society the case of a man forty-nine years of age with epithelioma who gave a history of hoarseness of five years' standing. The condition had been diagnosed as tumor of the cord, but his family physician had persuaded him not to have anything done to his throat. Dr. Berens removed intralaryngeally a large mass which occupied the anterior two thirds of the vocal cord, supposing it to be a papilloma. Dr. Jonathan Wright, however, pronounced it epithelioma, and, after consultation with Dr. Delavan, he slit the larynx, having in mind to do what Dr. Cohen referred to — raising the mucous membrane and periosteum, but, finding that the periosteum was more adherent over the center of the false cord, he took out the wing on that side. With the application of adrenalin he blanched the mucous membrane and had an absolutely dry wound to work upon in the larynx, and made a rapid operation. The patient carried the tube only three days, and made an uneventful recovery, with a very useful voice. He is an insurance agent and is busily engaged in his work.

Dr. Cornelius G. Coakley, New York, reported the case of a patient with a history of hoarseness for two years, and who presented himself with the appearance of malignant involvement of the right vocal cord. The perichondrium was soft, and there was no use in leaving it. The whole of the cartilage and the right half of the larynx was removed. The patient did well and returned to his home in the West, but later a contraction occurred and a tracheotomy tube had to be inserted. Two weeks ago there were signs of trouble and sections were made and pronounced by the pathologist to be carcinoma. The man has

involvement of the glands of the neck and the arytenoids, and he had advised against further operative procedure. Four or five years ago he had done a hemilaryngectomy, and a year since he had seen this patient with an apparent good result. In another case two years after operation there appeared to be a recurrence, but examination showed it to be a cyst, which was removed, and the patient has been all right since.

DR. ARTHUR W. WATSON, Philadelphia, said that Dr. Cohen had evolved this operation theoretically more than fifteen years ago, and demonstrated it on a dog, at which time he had the pleasure of assisting him. Shortly after that he wrote a paper on the subject for the Laryngological Association meeting in Boston, so there is no doubt that the method originated with him.

DR. BERENS said that he had failed to mention in the case he reported that the scar on the side of the larynx removed does not take up as much room as the true vocal cord would do in the position of rest, so there is no contraction where the cartilage was removed. The patient has the whole wing on one side.

DR. WATSON, referring to what had been said of taking out the wing where it involved the perichondrium, said that it had occurred to him that instead of taking out the cartilage and the perichondrium on the other side, it might be better to simply split it on the inner side, and leave that as an outer wall to the pharynx.

DR. SWAIN, New Haven, said that he did not understand whether Dr. Richardson had spoken of the formation of a cicatricial process, or by what means he got a loud tone. He himself had reported a case which had been three years without recurrence, and now, two years later, the patient is all right and can speak in a good clear voice. In this case he had removed the whole involved area, including the vocal cord, and there has been added in the way of a cicatricial formation a new band which is almost similar to the old vocal cord. It has a free clear edge with some range of motion, so that there is a pretty fair pair of vocal cords. He would like to know if that is the uniform result of the operation.

DR. MAYER, New York, reported the case of a patient who came to him with all the appearance of cancer of the larynx, in which he had refused to take off even a small piece for examination unless the patient were willing to have the whole removed if the growth proved malignant. At first the patient refused, but later agreed, and went into the hospital for examination. To Dr. Mayer's surprise it was found to be not malignant, the patient was put on antisyphilitic treatment, and is living to-day without operation. Another patient, now under observation, sixty years of age, presented himself with so much dyspnea that a tracheotomy had to be performed immediately. As soon as his physical condition warrants, the operation which Dr. Richardson has described will be performed.

DR. D. B. DELAVAN, New York, said that he had seen Dr. Berens' patient both before and after operation, and the results are in every way admirable. With regard to the question of diagnosis, he recently had a case operated upon in which two thirds of the tumor-like mass, as large as the end of a thumb, was sent to the pathologist for examination, the remaining mass being removed later at the same operation. The first fragment was reported to be a practically typical papillomatous growth; later, when the same pathologist had time to examine the second portion removed, he reported it "typical epithelioma." In this case we have an illustration of a condition in which the part of the growth reached from the larynx by any possible instrument showed no signs of malignancy, so that the examination of a large fragment removed in that way was misleading. The remainder of the growth was removed on the basis of operation for benign growth, but it proved malignant. Unfortunately the patient did not survive.

DR. CHEVALIER JACKSON, Pittsburg, said that he had a very beautiful series of drawings taken from a month to seven years after a thyrotomy which illustrate the point made by Dr. Swain. The band assumes the form and function of the cord to such an extent that it is quite customary for men to inquire which side was operated on. Usually the cicatricial band is quite vascular, and four or five years after operation it requires very careful examination to determine the operated side, if the arytenoid has not been injured or fixed before operation.

DR. RICHARDSON, Washington, closing the discussion, said that the patient has simply a rather hoarse voice. As Dr. Jackson had said, a band of tissue is developing. When first seen a month after operation there was nothing, last November it was commencing to show, and the last time he was seen the band was showing quite decidedly, just in line with the opposite cord. In time it will probably develop more fully.

## XX. REPORT OF A CASE OF RECURRENT PAPILLOMA OF THE LARYNX, EXTENDING OVER THIRTY YEARS, DURING WHICH TWO THYROTOMIES WERE PERFORMED.

FRANCIS R. PACKARD, M.D., Philadelphia.

The patient first came under Dr. Packard's observation in 1904. He was then sixty-six years of age and had had laryngeal trouble for twenty-four years. He was a very intelligent Englishman and had been an auctioneer until it became impossible for him to use his voice. In 1883 he had come to America for the express purpose of having his laryngeal condition treated by the professor of laryngology of the University of Pennsylvania at that time, the late Dr. Carl Seiler. Dr. Seiler diagnosed the trouble as multiple papilloma of the larynx, and removed enormous portions of the growth. The patient went to New York in 1884, and was treated by many laryngologists, who continued removing masses from his larynx until July, 1885, when Dr. Gerster performed a thyrotomy and removed a large mass, which under the microscope proved to be papilloma. Dr. Packard removed masses of a similar character at numerous subsequent sittings. In February, 1905, Dr. Le Conte, at the Pennsylvania Hospital, divided the thyroid cartilage anteriorly once more and removed enormous masses, the microscopic examination showing once more nothing but benign papillomatous tissues. Since that time he has been very much better. At present he can talk quite distinctly, although his voice is very husky, but the larynx is free from any evidence of return of the growth. He is now seventy-two years of age, a strong man, and apparently perfectly healthy.

The interesting points in the case are: (1) The long time during which the patient has been under observation and throughout which intelligent treatment has been directed to the relief of the condition. (2) The fact that throughout that period, as far as can be known, there has been no change in the nature of the neoplasm. (3) The fact that this growth is so typical as to etiology, occurring in an auctioneer; as to growth and microscopic appearance; and, lastly, as showing no tendency, in spite of repeated operative interference and traumatism, to undergo any malignant degeneration.

DR. SAMUEL JOHNSTON, Baltimore, said that with papilloma of the larynx, especially in children, we get excellent results in many instances. He then cited a case of a child who came to him suffering great stridor, and with only a chink to breathe through, who was

successfully treated with applications of colloid of zinc, 10 gr. to the ounce, and 2 gr. of thyroid extract three times a day to increase its nutrition. In a very short time the child began to improve and in three months the papilloma had disappeared, the child had gained in weight, and the voice was completely restored. He has treated two other cases in adults, and his assistant has treated a child, with the same results. He hoped that others would give this treatment a trial.

Dr. Delavan said that the type of papilloma described by Dr. Packard, and the small not very active growth that Dr. Johnston had to deal with, are different diseases altogether, although histologically they may show the same appearance. Some years ago he had recommended alcohol for the type of growth mentioned by Dr. Johnston, and others employ other remedies, but there is a type which cannot be cured by such measures.

Dr. Charles W. Richardson, Washington, said that many of these growths reach apparently a certain stage of reproduction, and if we keep on at them until they reach that stage they cease. He had had a case which bears out Dr. Johnston's case. In this instance the growth extended from the anterior commissure almost to the arytenoid, and which was removed in four or five weeks by frequent applications of the sound. Another patient had a similar course to Dr. Packard's case. He was not quite so old, but came under observation some years ago, and the result has been very satisfactory.

Dr. J. P. Clark, Boston, said that one or two points in Dr. Packard's case were unique. He has never known a case of papillomata in adults which began in adult life. From the history given by Dr. Packard this papilloma apparently began at forty. In a series of cases which he had reported some years ago the cases all began in childhood. It is also unique that a papilloma of the larynx in an adult should show such a strong tendency to recurrence. In his experience they have yielded very quickly to removal. In regard to papilloma of the larynx in children, as he had pointed out some years ago before the association, they may disappear without doing anything. In papilloma of the larynx it is difficult to say whether any given treatment is the cause of the disappearance or not. When the papilloma gets ready to go, it goes, but until the activity which causes it is removed, it will not be relieved by anything that is done for it.

Dr. W. E. Casselberry, Chicago, said that he had seen a number of cases of papilloma which originated after adult life. He thought that the description of two varieties of this disease is inadequate — he would say ten or more varieties. They range all the way from the circumscribed narrow base pedunculated growth to the persistently recurring growth which fills the larynx. He has had under observation for many years a case of the permanent type which commenced after thirty-five years of age. The patient is now well; that is, he is performing all his duties on the bench with a good voice, but every month some fragments are removed from his throat. At the Medical Congress held in Washington in 1899 he had proposed the galvano-cautery for the destruction of the base of the papilloma in the larynx in adults, and he has been using it ever since very satisfactorily.

Dr. W. K. Simpson, New York, said that it is well known that papilloma in children or very young adults are susceptible to many types of treatment. He himself had followed Dr. Casselberry's treatment with the cautery with very good results, but the best result he ever obtained was in the case of a young woman with a very extensive papillomatous growth which recurred after every type of instrumentation. He then applied pure lactic acid. The recurrences ceased with perfect restoration of the vocal cord and voice. He feels that this is one of the most effective escharotics we have.

Dr. H. L. Swain, New Haven, said that we all like to hear end results in these cases, and told of two patients seen upon whose larynxes he had operated many years ago. One, an adult, seen twenty years ago, then aged thirty-five, had a quantity of papillomatous growth which did not recur very rapidly, but every three or four years a little one was removed here and there; then, thinking that instrumentation might be the cause of the recurrence, he desisted for ten years. When seen this winter two or three are still present, but she is apparently getting on all right. On the other, the growth became so great that a thyrotomy was done, the growth removed and the base burned out with the Paquelin cautery. The growth did not recur and the patient passed from observation for five or six years, but when examined this winter she has two or three small growths. In both cases it seems better to avoid instrumental interference if possible.

Dr. E. L. Shurley, Detroit, said that he had had several of these cases in the last fifteen years, and in all of them had performed tracheotomy and removed the growth as far as possible. One had a thyrotomy. All have recovered. Ordinarily putting the larynx at rest is sufficient for the recovery of these cases.

Dr. W. K. Simpson, New York, said that in an adult where the traumatism resulted from excessive use of the voice, putting the throat at rest would probably cure it, for then the cause was removed.

Dr. Shurley said that the same principle would seem to apply to all papilloma in adults. The invention of the bronchoscope and Dr. Jackson's instruments have revolutionized procedures along this line, but there is some danger of losing the use of the mirror.

Dr. Myles, New York, said that the case reported by Dr. Packard did not take children into consideration, and then cited the case of an only child sent by its parents to a general surgeon, who operated by splitting the larynx. The child died of pneumonia a week later; if a tracheotomy had been performed the growth would probably have fallen away. He also told of another case, a woman nearly fifty, from whose larynx and trachea he had at different times removed 164 papillomata. She had diffuse papillomatous degeneration of the vocal cords, ventricular bands, epiglottis and a considerable area over the thyrohyoid area extending into the trachea. He had succeeded in making her breathe and talk comfortably, and there are only a few small growths left. They recur every year to a certain extent, but after a seance she is comfortable again.

Dr. A. W. Watson, Philadelphia, said that he wished to add his testimony to Dr. Casselberry's in regard to the value of the electrocautery. He has never met a case of papilloma in adults that did not yield to the galvanocautery, even such as the one described by Dr. Packard.

Dr. Packard said that he had epitomized the means employed. The patient was very intelligent and had had all kinds of applications tried; he asked particularly not to have any intralaryngeal work done if it could be avoided, for the condition had recurred after every such procedure.

### SUPPLEMENTAL REPORT ON OPERATIONS ON MALIGNANT GROWTHS OF THE UPPER RESPIRATORY TRACT.

Dr. Price-Brown, Toronto.

Dr. Price-Brown said that he had reported on these cases last year, but now wished to report again. The first case, in which he had removed three fourths of

the septum, had had no recurrence. The other two were young men who lived outside of Toronto and returned to him to report at Christmas time. They were feeling perfectly well, but in each there was a return of the growth, and he repeated the former procedure, and has since treated them once a month, or twice if necessary. The treatment does not interfere with their work in any way, and there is no hemorrhage after leaving the office. He does not take sections, for he believes it would be injurious to do so. They have both recovered by constant care and attention, and by elimination of the growth. Eventually it is probable that the recurrence will cease. The case that he operated on nine years ago — it is now years since he was last operated — is perfectly well. These two young men are perfectly well so far as appearance and feeling are concerned, but the growths recur occasionally.

XXI. BLACK TONGUE — LINGUA NIGRA VILLOSA.

CHARLES H. KNIGHT, M.D., New York. Read by title.

The paper gave a brief review of the literature, showing conflicting views of etiology, together with report of a typical case nearly a year in duration, occurring in a man of middle age, and undergoing spontaneous cure on abstention from the use of tobacco for two weeks. There is no evidence of malignant tendency; subjective symptoms are trifling, and local treatment is of doubtful efficacy. The affection must be regarded as curious rather than important, and doubtless often escapes observation. There are now on record upward of one hundred and fifty cases, yet while the clinical history is sufficiently clear, the causative factors remain obscure.

## Book Review.

*Nursing in Diseases of the Eye, Ear, Nose and Throat.* By the Committee on Nurses of the Manhattan Eye, Ear, Nose and Throat Hospital. Philadelphia and London: W. B. Saunders Company. 1910.

The opening paragraph of the preface of this book reads: "In looking about for a book on nursing which would serve as a textbook for the nurses in the Training School of the Manhattan Eye, Ear, Nose and Throat Hospital, we were unable to find one which exactly suited our purpose." "We" means the committee of nurses. This committee, not finding what they wanted, collaborated and compiled the book under review. The collaborators are three surgeons, one from each department, two assistant surgeons, the attending physician to the hospital and the superintendent of nurses.

The book aims to give the fundamental and necessary facts which a nurse training for the care of eye, ear or throat cases should know. For instance, in the section devoted to the ear, the first chapter deals with anatomy and physiology; the second, with the examination of the ear, — the general method and the instruments employed; and the third and the succeeding chapters take up the diseases of the ear and the medical and surgical measures needed for their relief. The chapters dealing with the eye and the throat are arranged in the same methodical way. Throughout the book especial stress has been given to the instruments needed for dressings and operations. The lists of instruments — "layouts" — ought to be a great help to the nurse who wishes to attain the maximum of usefulness in surgical cases.

The first section of the book, styled "The General Part," seems to the reviewer the freshest and most interesting. There are ten chapters, which deal in order with the germ theory of disease, antiseptics, disinfection of rooms and clothing, sterilization, the preparation of the operating room, the duties of the nurse at operations, the nurse's duties in emergencies, the management of troublesome children, the ideal nurse and her conduct in the sick room, and, finally, the feeding and care of infants.

The chapter on the management of troublesome children is novel and very practical. The chapter which follows, the ideal nurse and her conduct, is something of a sermon, but one that should prove stimulating and useful. There is much good sense in it. For instance, nurses are reminded that their coming into the household means a great increase in expense, so that it behooves them to be considerate. They are reminded also that unless they are tactful their arrival may cause a speedy discontent among the servants. A further warning might be given along this line, namely, that a nurse should never go into the kitchen if it is possible to avoid it.

Speaking of the conduct of the ideal nurse reminds the reviewer that a paragraph, if not a whole chapter, could be written on the horror of feeding nurses. It is well known that a nurse is often shamefully imposed upon, but, on the other hand, so is the mistress of the household. Often the best of nurses are brutally impolite when they sit at table with the family. The feeding of a typhoid patient may be hard, but the feeding of a nurse is often harder. The stony stare with which the food on the table is investigated is but a mild form of this impoliteness. This might be borne, but it is enough to break the heart of any housekeeper to face day after day the bird-of-Paradise air so frequently assumed by the nurse at her meals, and the pecking at her food which goes with it. The amount of food wasted by such a nurse is no small matter. I have often wondered what the home diet of nurses of this stamp might be. Ten to one it is not half as good as the food they rudely sniff at in the homes of their patients. If every training school would supply its nurses with a diet list which the majority of its graduates would eat, a list which the mistress of the house could ask for and follow, the cares which come to the household when sickness and the trained nurse enter it would be reduced one half.

The reviewer knows whereof he speaks; but to return to the book under discussion or rather under review. The book is admirably fitted to accomplish its purpose. Practical points which make for efficiency are emphasized. It gives nurses what physicians wish them to know. The volume is well printed and aptly illustrated. Some of the illustrations of instruments, however, are too small and too indistinct.

## MEDICAL AND HUMAN PROGRESS.

In the JOURNAL of Dec. 22, page 971, we printed a communication relative to an editorial in the issue of the JOURNAL for Dec. 8 on the "Report of the Massachusetts Tuberculosis Commission." Our correspondent takes particular exception to two things in this editorial: first, to our question as to the economic advisability of state subsidy for non-paying tuberculous patients; second, to our statement "that human progress is necessarily slow, that something must be left to natural processes which can be aided but not hastened." His objections, and the points upon which he makes them, seem of sufficient importance to deserve further consideration; and his opinions are in themselves of such weight as to carry even greater conviction than the arguments adduced in their support.

In regard to state subsidy, our correspondent makes the now familiar assertion that the actual saving of human life and efficiency by such a measure would far more than balance its cost, and that apart from all other considerations, it would, therefore, be a financial economy for the community. That every death from tuberculosis does cost a certain outlay in money is, of course, true, though this is not necessarily borne by the state; and the experience of Denmark and Sweden, cited by our correspondent, goes far to prove that it is really cheaper for the state to prevent tuberculosis than to take care of its victims after they have been infected by the disease. It still remains to be proved, however, that state subsidy is really the best and wisest method for such prevention. Though by no means positive that it is not so, we believe the question still sufficiently open to doubt, as a measure of expediency, to merit further discussion.

Our correspondent's second matter of comment results from a confusion of human progress and progress in scientific medicine. The latter has, indeed, been rapid and brilliant, and may be confidently expected to continue so; the former is much slower and more obscure, for it is dependent not on individual genius, but on the recognition and assent of all. It is often long before the discoveries of science are made effective by popular adoption. An example of this may be found in vaccination against smallpox, which, after more than a century of demonstrated usefulness, has still many bitter opponents, especially in this country. Another instance of this unreasoning popular prejudice against the application of medical truth has just come to hand in an article by Mr. B. O. Flower, in the current number of the *Twentieth Century Magazine*, entitled "The Truth about the Bubonic Plague Scare." This article declares that there never was a case of bubonic plague in San Francisco, assails the "arrogant insistence" of federal authorities as to its existence, and attacks the proposition for the establishment of a national health department as the work of "bureaucrats and political doctors." It should be noted that Mr. Flower is an enthusiastic advocate of Christian Science, whose flourishing growth in the United States is further evidence how far human progress is behind that of medical science.

Now it is unquestionably true that measures of sanitation and hygiene and popular education have greatly reduced the incidence and mortality of certain infectious diseases. That the extensive further enforcement of such measures will eliminate those diseases is at least open to doubt. In the first place, popular opinion is often opposed to such enforcement; in the second place, there is an irreducible minimum beyond which we can hardly hope to go by extension of sanitary prophylaxis. A single agent like smallpox vaccination, diphtheria antitoxin and possibly antityphoid inoculation does more to check preventable disease than all the sanitation in the world. General hygienic measures are well worth while, and their reasonable application is desirable; but they cannot be expected to eliminate the infectious diseases until human progress keeps better pace than at present with that of scientific medicine. Indeed, from the very constitution of human nature they cannot be expected to do so. Natural process in the eradication of the infections is the slow evolution of general immunity. Such process may be aided by prophylactic measures. The segregation of every tuberculate would limit the

risk of many persons, but it might not stop tuberculosis. For the attainment of that end there will probably also be necessary the natural development of an immune race, or the scientific discovery of some agent which is an actual and infallible cure for the disease.

These observations are not intended, any more than our previous editorial, as opposition to the plans proposed by the Tuberculosis Commission, which represent the mature judgment of experts and their laudable effort for the control of a great popular scourge which is worth fighting. They are merely suggestions that there are other aspects of that problem than those which have been emphasized by the commission, aspects which thoughtful persons should consider and weigh before committing themselves to the support of measures involving considerable expense and a debatable policy. We are appreciative of the comments in our correspondent's communication, which will be helpful in such consideration.

## THE CASE OF ANTITYPHOID INOCULATION.

IN last week's issue of the JOURNAL we published a communication relative to a previous editorial in which we commented on "the insidious dangers of typhoid fever and the seeming impossibility of its extermination by even the wisest sanitary provisions." Our correspondent justly objects to what he conceives as an implied disparagement of the value of the sanitary prophylaxis of typhoid, though in reality nothing was further from our intention than to make light of its importance. The fact remains, however, as our correspondent points out, that sanitation is often woefully inefficient, even in many highly civilized communities, and this inefficiency may jeopardize other communities whose standards are higher. The maintenance of perfect sanitation seems incompatible with human nature as at present constituted, and the best that sanitation has been able to accomplish is to reduce typhoid to a residual minimum. It is precisely that residue which antityphoid inoculation may help us to eliminate and thereby complete our conquest of the disease. Had all the cadets at Annapolis been inoculated, the recent epidemic would certainly have been much less in extent and severity and might have been entirely avoided. Reports from every reliable source unanimously emphasize the probably high protective value of antityphoid inoculation and the gratifyingly successful results of its application. In this issue of the JOURNAL, pages 1 to 8, our readers will find a valuable paper by Major F. F. Russell, of the United States Army Medical Corps, on "The Prevention and Treatment of Typhoid Fever with Antityphoid Vaccine." This article is followed by another and shorter article by Drs. Richardson and Spooner on "Antityphoid Inoculation as Introduced into Certain Training Schools for Nurses in Massachusetts." In this paper and in the latest monthly bulletin of the Massachusetts State Board of Health, the secretary, Dr. Mark W. Richardson, after presenting the statistics of a series of inoculations in ten Massachusetts hospitals, continues: "Our experience, therefore, covers 1,588 inoculations practised upon 405 individuals. As yet there have been no untoward results, and we believe that the inoculated individuals have acquired an increased resistance to typhoid infection which will last them for several years at least. We expect in the coming year to extend the influence of these inoculations, especially among nurses and others attendant upon the sick. Furthermore, we have strong faith that the procedure will, within a short time, find increasing favor with the general public, which, exposed as it is to many sources of infection, is in great need of specific protection."

The employment of so promising an agent in the fight against typhoid seems indicated by common sense and scientific reason, and we strongly advocate its extensive general adoption. That this will meet with vigorous objection on the part of a prejudiced public is unquestioned. That, however, does not vitiate its value. Nor does our advocacy of it mean that we should for a moment relax our efforts to secure and extend the provisions of sanitation. Both are needed in the conflict. How secure against smallpox should we be if we relied on quarantine and made no general use of vaccination? We heartily agree with our correspondent that we should "work for improved sanitation as a means of preventing typhoid," but we believe that we should also work with equal zeal for the more general use of that new and valuable agent of preventive medicine, — antityphoid inoculation.

## EUGENICS AND DIVORCE.

THE "doctrine and discipline of divorce" constitute a problem which vexed and perplexed mankind before the days of Milton and which has continued to do so ever since. So much has been written and said about it that further comment seems almost superfluous, yet divorce remains today one of the most serious questions of civilization, not so much in itself as on account of the

deeper considerations of ethics, justice, sociology and human frailty which it involves.

The increasing frequency of divorce is perhaps one of the aspects of this problem most frequently and familiarly commented upon. According to recently published vital statistics of Massachusetts for 1909, there were during that year in this state 29,002 marriages and 7,050 suits for divorce filed or pending. To be sure, decrees were granted in only 2,384 of these cases, but the figures indicate marital infelicity in nearly 25% of all marriages. Since 1890, 7,635 divorces have been granted to husbands and 18,688 to wives. In nearly 50% of these cases the cause was desertion, in about 20% infidelity, in about 16¾% cruelty, in about 12½% alcoholic intemperance. In only one county of Massachusetts were there no suits for divorce during 1909.

In England, the problem of divorce has assumed such importance that in June, 1910, its consideration was entrusted to a specially appointed Royal Commission, at whose sessions, terminating on Dec. 22 last, much interesting and instructive evidence was produced. Apparently in the opinion of this commission the solution of the problem rests in eugenics, that ubiquitous modern science in which many are now prone to place all the millenial hopes of humanity. Moreover, one of the experts, testifying before the commission, declared that eugenics is a department of preventive medicine, thereby bringing divorce within the category of diseases with which it becomes the duty of physicians to deal. Whether the responsibilities of the profession be not already great enough but that it must undertake this proposition also, and attempt the regeneration of mankind *en bloc*, remains to be determined, but at any rate this turn of the argument gives a medical aspect to the problem of divorce which merits at least theoretic consideration.

The specific recommendation made by the advocates of eugenics is the prevention of propagation among the unfit, particularly the insane, the tuberculous and the intemperate. This they propose to accomplish by the establishment of marriage registration bureaus, at which all persons "intending matrimony" must file certified statements of their personal health, habits and heredity, and undergo physical examination. Without approval by these bureaus no marriage licenses should be granted. Doubtless such a system, if established, might to some extent prevent propagation among the unfit, and lead to a certain physical improvement of the race. Whether it would operate as a check on divorce remains an open question, for the conditions which lead to domestic unhappiness and divorce seem in many instances more profound and dependent on subtler causes than could come under the jurisdiction of such a system. The crux of the whole matter lies in the essence of human nature. As Professor Geddes remarked in another connection: "What was decided by the prehistoric protozoa cannot be annulled by act of Parliament." The solution of the problem, if any there be, like the solution of most human difficulties, would seem to lie in education rather than in legislation. Meantime the possibilities of active eugenics, whether as bearing on divorce or on preventive medicine, deserve consideration by physicians and by other thinking persons, for they form a promising part of the unthreshed material of the times.

## LIABILITY OF MUNICIPALITIES FOR WATER POLLUTION.

It is reported from St. Paul, Minn., that the Supreme Court of Minnesota has recently rendered an important decision relative to the liability of municipalities for the death of citizens from disease contracted by drinking polluted city water. Following a recent epidemic of typhoid fever at Mankato, Minn., which the Minnesota State Board of Health determined to be due to the pollution of the city water supply by sewage, the widows of two men who died of the disease brought suits for damages against the city on the ground that their death was due to the negligence of city officials. The city demurred, and this demurrer was appealed to the Supreme Court, which has decided that such suits can be maintained against a city and that the city is liable, if damages can be proved. This decision seems of considerable importance as a precedent, and suggests possibilities of much litigation against municipalities for alleged negligence in the discharge of government functions from which damage to individuals may directly or indirectly have resulted. It is tantamount to making everybody legally responsible as his brother's keeper.

## RESPONSIBILITY OF PHYSICIANS FOR VITAL STATISTICS.

The importance of reliable vital statistics as a basis not only for scientific research, but also for the hygienic and sanitary measures of preventive medicine and for many sociologic reforms, is self evident. The frequent unreliability of vital statistics, even in enlightened communities, is

also unfortunately well known, and it must be confessed that the fault for this often lies with physicians, whose failure to report births and deaths with promptness and accuracy of detail vitiates otherwise valuable data. Uniformity of method in such reports and records over large registration areas is likewise an essential. The United States Census Bureau has for some time advocated the extension of such a uniform system throughout the country, and in pursuance of this policy has issued for physicians a pocket leaflet of reference to the International List of Causes of Death. In a recently published letter transmitting this leaflet to the secretary of the Department of Commerce and Labor, the director of the Census Bureau makes pertinent comment thereon, and on the general subject of vital statistics which seems to deserve repetition. He writes:

"It seems to me that there is almost nothing more important in the entire field of statistics than vital statistics, because of their direct bearing upon the health and consequent welfare of the people. It certainly is both strange and shameful that the United States should be so far behind the other leading countries of the world in the registration of deaths, and even more so in the registration of births. I hope for the cordial interest and support of the entire medical profession of the United States in making our statistics of causes of death, as received from the registration area, of the utmost accuracy, and in helping to extend the area of complete registration both for births and deaths until the vital statistics of the United States shall be second in completeness and usefulness to those of no other country.

"The physician's responsibility is usually confined to the correct statement of the cause of death, but he may in some instances fill out the entire certificate, or he may note errors in the statement of personal particulars, the correction of which will be of service to statistical accuracy, as well as insuring more truthful legal records. Hence his interest is solicited in the completeness and correctness in all respects of all certificates passing through his hands, and more especially in the correct statement of sex, color, marital condition, age, occupation, birthplace, birthplace of father, birthplace of mother, and length of residence, when the latter is required.

"Age is of special importance, and as a check on the accuracy of the statement the date of birth is also required. For infants under one day old, state the hours, or even the minutes if less than one hour old. This is necessary in order that stillbirths may be distinguished with absolute precision from deaths of children born alive.

"Precise statement of occupation is very important, so that the relative healthfulness of various pursuits can be known. The statement should include: (*a*) Trade, profession or particular kind of work and (*b*) general nature of industry, business or establishment in which employed (or employer)."

That there are states in the Union which have no registration of vital statistics, and others in which that registration is absolutely inadequate, emphasizes the importance of these comments. Their moral should be taken to heart by every physician in the country, for with physicians rests the ultimate responsibility for vital statistics.

## MEDICAL NOTES.

YELLOW FEVER IN NICARAGUA. — It is reported from Washington, D. C., that a fatal case of yellow fever occurred last week at Managua, Nicaragua.

OPIUM SMUGGLING IN THE PHILIPPINES. — Report from Manila, P. I., states that on Dec. 29, 1910, two merchants of that city were sentenced by the Supreme Court to two years' imprisonment and a large fine for opium smuggling. Both had served a previous sentence for a similar offense.

BUBONIC PLAGUE IN MANCHURIA. — Report from Harbin, Manchuria, states that the epidemic of bubonic plague is extending in that country. In Fudziasian, a Chinese suburb of Harbin, there are said to have been 98 new cases and 28 deaths of the disease on Dec. 25, 1910; and on Dec. 26, 68 new cases and 17 deaths.

CHOLERA RIOTS IN MADEIRA. — Report from Lisbon states that the epidemic of Asiatic cholera continues to prevail in Madeira, and that there is vigorous opposition on the part of the native inhabitants to all sanitary measures to prevent its spread. The Twenty-Seventh Portuguese Regiment of Infantry is now stationed in the island to check the serious rioting which has occurred as a result of this popular prejudice.

IMPURE FOODS AND DRUGS IN COLORADO. — Massachusetts is not the only state troubled by impure foods and drugs. It is reported that the Colorado State Board of Health has found 57 firms, mostly in Denver, selling adulterated and misbranded sausages, and adulterated ice cream. One brand of headache wafer, "guaranteed to contain no harmful substances," was found on examination by the board to contain 5 gr. of acetanilid.

Death of a Leper. — It is reported from Aiken, S. C., that Miss Mary V. Kirk, who has been under quarantine at her home in that city for over two years with leprosy, died there on Dec. 27, 1910. She is said to have contracted the disease nineteen years ago while in Brazil as a missionary.

New Hospital in Chicago. — On Dec. 30, 1910, the new Iroquois Memorial Emergency Hospital in Chicago, erected to the memory of those who lost their lives at the Iroquois Theater fire on Dec. 30, 1903, was formally presented to the city. It is a four-story fireproof building of twenty rooms.

A Living Centenarian. — George H. Hawes, of Saugus, Mass., who is said to have been born on Dec. 26, 1810, at Halifax, N. S., celebrated last week the supposed centennial anniversary of his birth. He came to Saugus as a child, and was married there in 1850. He has been a widower for the past twenty years. His health is excellent, and he is said to be able to read a newspaper without glasses.

Horse Flesh as Human Food in Germany. — The extent to which horse flesh is used on the continent of Europe as human food is not generally realized in America. It is reported from Germany that the city of Berlin has recently appropriated the equivalent of $89,000 for the construction of a new abattoir especially for the sanitary preparation of horse flesh. It is stated that 12,500 horses are annually slaughtered in Berlin for this purpose.

Pure Milk in Turkey. — The advent of the new Turks has apparently led to many salutary reforms in the Ottoman Empire. A report from the United States consul at Salonica describes the establishment in that city of an admirable system for the municipal inspection of milk, whereby the contents of every can is daily tested and the can then officially sealed until its delivery to the consumer.

Bequests to London Hospitals. — Report from London states that the will of the late Henry Silver of that city, formerly on the editorial staff of *Punch*, who died on Dec. 3, 1910, makes the following bequests to London medical charities: To the Royal Free Hospital, £50,000; to the Royal Victoria Hospital for Children, Chelsea, £25,000; to the Great Ormond Street Hospital for Children, £25,000; to the West London Workshops for the Blind, £2,000. It is significant to note that over one fifth of Mr. Silver's large estate is consumed by legacy and inheritance taxes.

Poliomyelitis in Rhode Island. — The Rhode Island State Board of Health has just published statistics of the epidemic of poliomyelitis which prevailed in that state during the past spring and summer. Since March, 1910, there have been reported in Rhode Island 206 cases of the disease, 113 in males, 93 in females. The ages of the patients ranged from one month to twenty-four years. There were 26 fatal cases, of which the majority were between one and five years of age.

Medical Inspection of Schools in England. — A recently published report of the chief medical officer of the British Board of Education states that in England there are at present 986 medical inspectors of schools, of whom 73 are women. Of 6,000,000 school children in the public elementary schools of England and Wales, about 30% have bad teeth, 10% have defects of vision, 8% have enlarged tonsils or adenoids, 2% have suppurative otitis media, 1% have tuberculosis and 1% ringworm. Defective vision, especially myopia, is said to be commonest among Hebrew children.

Determination of Deterioration in Maize with Reference to Pellagra. — In a recently published bulletin (No. 199) of the Bureau of Plant Industry of the United States Department of Agriculture, Mr. Otis F. Black and Dr. Carl L. Alsberg present the results of their "critical study of the methods of detecting products of deterioration in corn and corn meal," which they regard "as a necessary preliminary step in the investigation of the alleged relation between spoiled corn and pellagra." The importance of determining this relation prior to any attempt to eradicate the disease is obvious, and the researches of the authors into the chemical and biologic methods of testing corn and corn products should be of value not only in this respect, but to hygienists, economists and agriculturists in general.

American Association for the Advancement of Science. — The sixty-second annual convention of the American Association for the Advancement of Science was held last week in Minneapolis, Minn. Numerous papers of interest and value were presented before the sessions of the several sections. In his address as vice-president of the section on physiology and experimental medicine, Dr. Charles S. Minot, of Boston, discussing

"The Method of Science," commented particularly on the pre-eminence of the sense of vision as the supreme human instrument of research, and on the surpassing excellence of English as a scientific language. Dr. Burton R. Rogers, in a paper on "The Control and Eradication of Animal Tuberculosis," pointed out that one cause of the present high cost of meats is the expense involved in their inspection and in the destruction of diseased animals.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 3, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 62, scarlatina 36, typhoid fever 11, measles 58, smallpox 0, tuberculosis 55.

The death-rate of the reported deaths for the week ending Jan. 3, 1911, was 16.35.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Dec. 31, 1910, was 232, against 261 the corresponding week of last year, showing a decrease of 29 deaths, and making the death-rate for the week, 17.96. Of this number 116 were males and 116 were females; 228 were white and 4 colored; 139 were born in the United States, 92 in foreign countries and 1 unknown; 55 were of American parentage, 151 of foreign parentage and 26 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 51 cases and 4 deaths; scarlatina, 33 cases and 1 death; typhoid fever, 9 cases and 0 deaths; measles, 55 cases and 0 deaths; tuberculosis, 52 cases and 22 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 46, whooping cough 2, heart disease 32, bronchitis 3. There were 9 deaths from violent causes. The number of children who died under one year was 26; the number under five years, 43. The number of persons who died over sixty years of age was 74. The deaths in public institutions were 81. Cerebrospinal meningitis, 2 cases. Acute anterior poliomyelitis, 1 case.

Of the above infectious diseases the following were non-residents: Consumption, 1 case. Scarlet fever, 4 cases.

Deducting deaths of non-residents, the total is 208 and the death-rate is then 16.10.

BEQUEST TO THE DEACONESS HOSPITAL. — Among other charitable bequests in the will of the late Lucy A. Sanger, of Peabody, Mass, filed for probate at Salem, Mass., last week, is one of $300 to the New England Deaconess Home for hospital work.

PENALTY FOR FAILURE TO REPORT A NOTIFIABLE DISEASE. — For failure to report to the Boston Board of Health a case of ophthalmia neonatorum, a physician of this city was last week fined $50 before the central municipal court. The sentence, however, was suspended and the defendant placed on probation.

MEETINGS OF SCIENTIFIC SOCIETIES AT NEW HAVEN. — On Dec. 28, 29 and 30 of last week were held in New Haven, Conn., the annual meetings of the American Society of Biological Chemists, the American Physiological Society and the American Pharmacological Society. A total of over one hundred members were present. There were both individual and joint meetings of the several societies.

NEW OFFICERS OF THE MILK AND BABY HYGIENE ASSOCIATION. — At a recent meeting of the Boston Milk and Baby Hygiene Association, the following officers were elected for the ensuing year: President, Dr. Charles W. Eliot; vice-presidents, Dr. Milton J. Rosenau, Mr. Horatio A. Lamb and Mrs. Charlotte Barrell Ware; secretary, Dr. Walter B. Cannon; treasurer, Mr. Arthur H. Brooks. The association is now maintaining in Boston nine milk stations, which not only supply milk at a nominal cost, but conduct an extensive and valuable work in the supervision of the feeding and the general health of babies, and in the education of mothers in their care.

TWO CENTENARIANS. — Frank King, who died of cerebral hemorrhage at Grafton, Mass., on Dec. 29, 1910, is said to have been born on Dec. 5, 1806, in Quebec, Canada. He was twice married, and had 31 children, 18 by his first wife, 13 by the second. He also had 26 grandchildren and 26 great-grandchildren. His life displayed a prolific vigor reminiscent of Augustus the Strong.

Mrs. Catharine Cuddihy, who died at Northampton, Mass., on Dec. 31, 1910, is said to have been born in 1803 in Ireland. She came to Northampton in 1835. She was a widow.

CONVICTIONS FOR ILLEGAL SALE OF MILK AND DRUGS. — Before the South Boston municipal court last week a milk dealer of Charlestown, Mass., was fined $100 for having in his possession, on Nov. 29, 1910, with intent to sell, skimmed milk not marked as such.

Before the Boston central municipal court last week, a clerk from a drug store in this city was fined $50, on two counts, for illegal sale of morphine. Another was fined a like amount for illegal sale of cocaine.

Before the Dedham (Mass.) police court last week, a dealer from Norwood, Mass., was fined $5 for illegal sale of cigarettes to a minor; and another dealer from the same town was also fined $5 for failure to post properly, as required by law, the notice relative to the sale of tobacco to persons under legal age.

Report of Massachusetts State Board of Pharmacy. — The twenty-fifth annual report of the Massachusetts State Board of Pharmacy, recently published, shows that during the past year 27 new drug stores have been established in the state and 16 discontinued, a net gain of 11. Of 495 candidates examined during this time, 111 were granted certificates as registered pharmacists, 143 as assistant pharmacists, and 241, nearly 50% were rejected. The report points out that, as indicated by this high percentage of rejections, there is great deficiency among many of the candidates, and suggests, though it does not definitely recommend, that it would be advisable to require that such candidates must hold, as a prerequisite to entitle them to examination, a diploma from some recognized school of pharmacy as evidence that they have had a suitable training in the science and art of pharmacology.

A New State Psychopathic Hospital. — Construction has begun upon the new State Psychopathic Hospital on Fenwood Road in the Longwood district. The hospital will contain one hundred beds and will receive, classify, and treat the acute insane of the Boston metropolitan district. The institution is non-custodial in character and recalls in general plan the modern general hospital, emphasizing the modern conception of insanity as sickness. Space has been provided for an out-patient and social service department to perform the important work of handling mild and incipient cases, and particularly children, that may be referred to the hospital from neighboring institutions. Dr. E. E. Southard has been appointed director. The institution will probably open in 1912.

### NEW YORK.

Bequests. — By the will of the late George L. Fox, a well-known Brooklyn lawyer, several hundred thousand dollars are bequeathed to charities in Brooklyn. The Eastern District Hospital and Dispensary is to receive $100,000, and among the other institutions favored are the following: St. Catharine's, St. Mary's, the German and the Jewish hospitals, each $25,000, and the Brooklyn Hospital, $20,000. Twenty thousand dollars is also left to St. John's Hospital, Long Island City, and $10,000 to the New York Ophthalmic and Aural Institute.

Among numerous charitable bequests in the will of the late Morris J. Blueu, of New York, are $2,000 each to the Hospital for Deformities and Joint Diseases, New York, and the National Jewish Hospital for Consumptives at Denver.

Death-Rate. — The death-rate in the city for 1910, it is announced, was the lowest of any year in the records of the Health Department. The rate was 15.98, as against 16 in 1909.

A Chinese Leper Set Free. — A Chinese leper who has been kept for some time at the tuberculosis hospital, Passaic, N. J., has now been set free by the Passaic Board of Health and allowed to return to his laundry business. City Sanitarian Nelson Elliott advised the health board that in his opinion leprosy is not communicable in this climate.

A Tuberculosis Hospital for Employees of the Metropolitan Life Insurance Company. — Approval has been given by the State Commissioner of Health and the local health officer, Dr. J. S. White, to the application of the Metropolitan Life Insurance Company of New York for the establishment at Mount McGregor, Saratoga County, of a hospital for the treatment of its employees affected with tuberculosis. The hospital was opposed by residents of Saratoga Springs, who contended that it would injure that village as a summer resort. In the course of their opinion the health officers say: "The most serious objection that is urged is the possible damage to the property interests of Saratoga Springs and to the mineral springs. It is easy to dispose of the sewage from such an institution, and any possible contamination of any waters can be prevented. Hospitals for the treatment of tuberculosis must be established in the rural districts. Practically every county in the state is considering the construction of one. The educational measures which are being carried on in regard to this disease will soon drive from people's minds the fear which is based on ignorance." The site selected for the institution is eight miles from Saratoga Springs.

SANITARY CONDITION OF SUMMER RESORTS. — During the past season the work of inspecting the sanitary condition of summer resorts was actively carried on by the State Department of Health. This year the work undertaken by the engineering divison of the department has consisted to a considerable extent in the reinspection of resorts inspected in previous years and at which unsanitary conditions were found and made the subject of letters addressed to the proprietors. Those reinspections, covering some 260 resorts, were completed for the Adirondack, Catskill and Finger Lakes districts, and, in addition, 170 original inspections were made in these and in the St. Lawrence and Champlain districts. In sixteen out of forty-three resorts with faulty conditions inspected in 1908 and reinspected in 1909 it was found that in five the unsanitary conditions had been fully corrected and that at seven improvements were under way which will remove the grounds for criticism, while at four no steps had been taken to correct the conditions. These were the Raquette House, Raquette Lake; the Saranac Club, Upper Saranac Lake; the Lake View House, Blue Mountain Lake, and the Cascade Lakes Hotel, Cascadeville.

"THE TEN COMMANDMENTS FOR HANDLING GARBAGE WITHOUT NUISANCE." — One of the addresses at the tenth annual conference of sanitary officers of the state of New York, recently held in Buffalo, was by Dr. P. M. Hall, health commissioner of Minneapolis, who announced as his title, "The Ten Commandments for Handling Garbage without Nuisance." In the course of it he stated that for the last three and a half years the city of Minneapolis has been handling garbage thus without nuisance at the can, in the wagon, upon the street or at the disposal plant. Before being placed in the can, which has an overlapping, self-locking cover, the garbage is drained of moisture and wrapped in paper (such as is brought by the butcher, the grocer and the baker with their wares). In this way it is so reduced in bulk and the process of putrefaction is so retarded that collections of once a week are often sufficient, even in summer — a great saving in the cost of collection. The garbage wagon-box is so constructed that it can be lifted off the truck and the load is dumped directly into the hopper at the disposal works. Through the burning of the garbage the city produces enough steam to operate all of its machinery and to heat and light the group of workhouse buildings, the superintendent's house, the tuberculosis hospital and two greenhouses. It is the intention of the authorities to place near the crematory all the hospitals for contagious diseases, so that they may be lighted and heated in the same way.

## Current Literature.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

DEC. 24, 1910.

1. *ARNOLD, H. D. *Importance of a Low Protein Diet in Chronic Nephritis.*
2. *DEAVER, H. C. *Appendicitis in Childhood, with a Report on Five Hundred Cases.*

5. CAFFREY, A. J. *Sodium Cacodylate in Syphilis.*
6. LEWIS, D. D. *Trapezius Transplantation in the Treatment of Deltoid Paralysis.*
7. HUNTLEY, V. F. *Congenital Dislocation of the Shoulder-Joint.*
8. SUTTON, R. L. *Sporotrichosis in America.*
9. MCRAE, F. W. *Conservative Surgery of the Pelvic Organs and the Lower Abdominal Walls.*
10. HAMILL, S. M., AND BLADSPAN, K. D. *Diagnosis and Treatment of Chronic Intestinal Indigestion in Children.*
11. HAGGARD, W. D. *Nitrous Oxide and Oxygen Anesthesia.*
12. TORRANCE, G. *Anesthesia in Traumatic Surgery.*
13. *WOOD, H. J. *The Comparative Danger of Ethyl Chloride as an Anesthetic.*
14. PETTIT, R. T. *Prevention of Hemorrhage in Pulmonary Tuberculosis by the Administration of Autogenous Vaccines.*
15. LEWIS, J. S. *Tincture of Iodine for the Umbilical Cord.*
16. SHEAFF, P. A. *A Simple Method for Measurement of Blood Cells.*

1. Arnold believes that in the severer or advanced cases of chronic nephritis the protein food should be limited to 50 gm. daily. Ninety gm. should be the limit in any case. His objection to the exclusive milk diet lies in the fact that if sufficient nutriment be supplied an excess of protein must be taken. It would require 3,000 ccm. of milk to supply the proper number of calories, and this amount of milk would contain 120 gm. of protein, which is much in excess of the maximum amount desirable for such cases.

2. Deaver states that appendicitis in children occurs with increasing frequency from birth to puberty, and is more common in males. It runs a rapid and severe course in children more often than in adults. Infantile appendicitis is more frequent than is generally believed. All cases of abdominal troubles in children should be regarded as appendicitis until proven otherwise. If the case is operated within the first twenty-four hours the mortality is practically *nil*. Operation is even more suitable for children than for adults. The Fowler position must not be maintained for more than thirty-six hours in drainage cases, lest intestinal obstruction occur. In presence of numerous adhesions in these obstruction cases ileocolostomy is the best procedure.

13. Wood condemns the freedom with which ethyl chloride is being used by inexperienced persons, with the idea that it is as safe as nitrous oxide. He believes that its wholesale use by dentists is nothing less than criminal. It is two hundred times as dangerous as gas. [E. H. R.]

11. *BASS, C. C., AND WATKINS, J. A. *A Quick Macroscopic Typhoid Agglutination Test.*

2. Swift's observations, which are not of very great extent, show a certain parallelism between clinical symptoms, efficiency of treatment and intensity of the Wassermann reaction. They point to injections as the most efficient method of administering mercury, and seem to show that the Wassermann reaction is the best guide to the length and severity of treatment required in each case.

6. This paper simply describes the apparatus and method used in obtaining duodenal contents, and gives some interesting tables which show the effect upon the quantity and activity of the duodenal juices of certain foods and drugs.

7. Austin and Frothingham, by injecting first dead, then live, typhoid bacilli into rabbits, developed in the rabbit's blood a power to agglutinate typhoid bacilli in a dilution of 1 to 20,000. The serum from these rabbits, if injected intravenously into other rabbits to the amount of 1 ccm. for every 750 gm. weight, conferred within a few hours a transitory agglutinating power in a dilution of 1 to 300 or 400, which is considerably higher than the agglutinating power usually acquired by human beings during the disease. Although this power to agglutinate so actively lasts only a few hours, it is suggested by the writers that in typhoid fever intravenous doses of serum, given every few hours, may confer so great an agglutinating power that material benefit will result.

11. Bass and Watkins describe a test to supplant the Widal reaction which, if it is proved accurate, must be universally adopted. A permanent solution of dead bacilli in weak liquor formaldehyde and 1.7% salt solution is used. One quarter of a drop of blood is mixed on a slide with one drop of water until it is dissolved. To this is added one drop of the standardized bacterial suspension, and the slide is gently agitated for two minutes. Within this time, if the blood possesses the power of agglutination, a "mealy grayish sediment" appears. If the test is negative, the solution remains clear. The authors base their claims for accuracy on "more than 100" comparisons with the Widal reaction and more than a year's clinical experience. [G. G. S.]

9. JAMIESON, J. G. S., AND LAUDER, J. M. *Case of Fatal Trichocephaliasis in a Child.*

2. Shaw, in a general way, discusses high blood pressure and its causes. He describes the use of the instrument to determine the pressure and urges frequent examinations rather than dependence on one observation. He goes over the theories of the causes of hypertension, mechanical and clinical, and briefly discusses the treatment.

4. French discusses the present deplorable lack of control of venereal disease in England, and suggests certain remedies for this state of affairs, particularly that of making such diseases notifiable. He believes that England, as far as the control of prostitution is concerned, is fifty years behind the continent of Europe. [J. B. H.]

## THE PRACTITIONER.

### NOVEMBER, 1910.

1. *CROOM, H. *Pyometra.*
2. *LANE, W. A. *The Use of Plates and Screws in the Operative Treatment of Fractures.*
3. MURRELL, W. *Some Points in the Modern Treatment of Rheumatism.*
4. *NICOLL, J. H. *Congenital Hypertrophic Stenosis of the Pylorus, with Special Reference to Its Treatment.*
5. MCDONAGH, J. E. R. *The Etiology, Treatment and Pathology of Venereal Diseases as We see Them Today, with Special Reference to "606."*
6. *ADAMS, J. E. *The Clinical Aspect of Intussusception.*
7. HURRY, J. B. *Vicious Circles associated with Diseases of the Eyes.*

9. BARTON, G. A. H. *The Open Method of Ether Administration, with Some Modifications.*
10. MULLOY, D. *The State Prevention of Tuberculosis.*
11. HOWELL, A. *Primary Diphtheria of External Urinary Meatus.*
12. MATTHEWS, H. *Pulmonary Edema and Death.*

1. Croom classifies pyometra (1) as it occurs in children; (2) in virgins, (*a*) apart from hematometra and (*b*) resulting from hematometra; (3) pyometra from acquired atresia after development of catamenia; (4) from cancer; and (5) from senile endometritis. He discusses these various forms of pus in the uterine cavity as to etiology, diagnosis, prognosis and treatment.

2. Lane believes that the guide to treating fractures by operative interference or by the ordinary methods of splints is whether or not it is of primary importance to restore the fractured bone or bones to their normal form. Absolute asepsis is necessary to success in the operative treatment. He describes the technic of his method with diagrams and illustrations of instruments. He discusses in detail this method of treating fractures about the ankle-joint, fractures of the tibia and fibula, the patella, femur, and of the upper extremity.

4. Nicoll discusses the treatment of hypertrophic stenosis of the pylorus in infancy with special reference to nine cases of his own. He goes into the details of dietetic and surgical procedures. The three essentials to success in treatment are (1) a skilled surgeon who does not take more than thirty minutes to perform a posterior gastro-enterostomy; (2) a family physician who is alive to the fact that there are cases of this kind only early surgical interference can cure; and (3) a good nurse.

6. Adams analyzes one hundred consecutive cases of intussusception, especially from the clinical point of view. He discusses the length of history of the trouble, age, seasonal incidence, preceding irregularity of the bowels, anatomical abnormalities and injury. As to symptoms, pain was the most constant, with vomiting next; he discusses the frequency of passage of blood per anum, constipation and diarrhea, abdominal distention, rigidity, tumor and its nature. In 27 cases the apex of intussusception was felt per rectum. He gives the details of the operative treatment in this series. Celiotomy and reduction by manipulation was done in 76 cases, with 53 recoveries and 23 deaths. [J. B. H.]

## EDINBURGH MEDICAL JOURNAL.

### NOVEMBER, 1910.

1. *MACEWAN, D. *Bier's Treatment by Venous Hyperemia.*

2. *HEARD, J. D. *The Significance of Transient Cerebral Crises and Seizures, as Occurring in Arteriosclerotics.*
3. *FOGGIE, W. E. *Congenital Dextrocardia. Cor Triloculare Biventriculare.*
4. COMRIE, J. D., AND FRASER, J. S. *The Frequency of Sphenoidal Sinus Suppuration.*
5. LAWRENCE, H. R. *Scopolamine-Morphine as an Obstetric Anesthetic.*

1. MacEwan summarizes his opinions as to the value and use of the Bier hyperemic treatment as follows: (*a*) In closed tuberculosis venous congestion is limited and uncertain in its effects and may do harm. In open tuberculosis it is often of benefit. (*b*) In circumscribed inflammation, boils, carbuncles, etc., it acts well, especially if the suction method is used. (*c*) ) It acts less favorably in spreading inflammation. (*d*) It gives good results in gonorrheal arthritis, but should be used with caution if there is pus in the joints. (*e*) It is contra-indicated in erysipelas and is of uncertain value in osteomyelitis. (*f*) It acts beneficially in infected wounds.

2. Heard gives the details of four cases of arteriosclerosis in which transient cerebral crises and seizures were frequent and then gives an interesting and careful discussion of this subject as to the local pathology, etiology, diagnosis and treatment, with special reference to the work of others along these lines. There is a full bibliography.

3. Foggie presents a case of congenital dextrocardia and then discusses this interesting condition as to the heart defect which was present and the heart displacement. He mentions the other cases of cor triloculare which have been reported. As to the cardiac displacement, he gives the details of the various extrinsic causes of this condition, such as changes in the lung, diaphragmatic herniæ and antenatal inflammatory conditions. These he discusses. The second group of cases of this kind are due to intrinsic causes and are cases of true congenital dextrocardia. He gives a table of forty-six cases of true congenital dextrocardia which he has collected from the literature. He gives a long and complete list of references. [J. B. H.]

9. Fickler is reporting on a new compound of salicylic acid which is soluble in water. It is the sodium salt of aspirin, with the following formula:

$$C_6H_4 < \begin{matrix} O \cdot CO \cdot CH_3 \\ COON \end{matrix}$$

It has the advantage over aspirin of being soluble in water. He has used it in 58 cases with good results. Its action is like that of the other salicylates in that it reduces fever, is specific for acute articular rheumatism, has an analgesic action and causes sweating and diuresis. The only poisonous effects were in 4 cases, and those were such as might occur with any salicylic acid salt, namely, disturbance of digestion and ringing in the ears. [C. F., JR.]

13. BOLOGNESI, G. *Endothelioma of the Submaxillary Salivary Gland.*

1. Kraft proposes an ingenious method for arresting gastric hemorrhage. Laparotomy is done, and at a point 5 cm. above pylorus and midway between greater and lesser curvatures on anterior gastric wall a purse-string suture is placed, the wall incised and a gastroscope inserted. The purse-string is tightened about the instrument, the stomach inflated and the gastroscope lamp lighted. The stomach, seen from the outside, appears like a Chinese lantern, with the arteries clearly outlined as they traverse the wall. Bleeding points in these vessels appear as breaks in continuity or abrupt terminations, and may show a dark clot attached. A suture is put through stomach wall on the proximal side of each bleeding spot so found, and the serous coat sutured over the ligature.

3. Bayer writes again regarding his method of dilating the prostatic urethra. His instrument resembles a lithotrite, but is used by the opening of the jaws instead of by their closure. This is used repeatedly, until the symptoms of retention and spasm are relieved. Of his 11 cases, 5 showed complete cessation of symptoms, 2 were relieved, 2 were not followed, 1 came to prostatectomy, and 1, which had severe bleeding at the time, died two weeks later of ascending infection. There was severe bleeding in only one case, but slight bleeding in several. Bayer advocates this method in all cases of "chronic prostatic swelling, prostatitis and hypertrophy, with urinary retention, which are aggravated by the pressure of retained urine, but have no severe cystitis." It should not be used in malignant disease. But in all cases not suitable for radical operation, or in cases in which the operation is postponed, this treatment, he says, will give relief, if not complete cure. Bayer may have had a certain measure of success with this method, but it seems unlikely that such a procedure, which at best strikes one as being unsurgical, will get beyond the hands of its inventor. 12. Fink, F. *The Operative Replacement of Irreducibly Dislocated Thumbs.*

3. Kausch answers the question as to whether bilateral resection or unilateral extirpation of goiter is better by coming out absolutely for the former. The resection of a wedge-shaped piece from each lobe, as advised by Mikulicz, is easier, Kausch thinks, than the unilateral extirpation of Kocher, and escapes, furthermore, the danger of injuring the parathyroids or the recurrent laryngeal nerve.

4. Eichmeyer's article is mainly statistical, giving the case histories, operations and pathological findings of one hundred and fifty patients with operative disease of the biliary tract, and a minute analysis of these statistics.

7. The observations of Riem as to the final condition of nets woven of silver wire after having been sutured into the abdominal wall to close a hernial gap convinces one that their use is not only foolish, but dangerous. The silver becomes eroded, the diaphragm loses its shape and may possibly wander through the tissues until its loose ends of wire puncture an artery.

8. Kaczvinsky reports 23 laparotomies (12 appendectomies and 11 operations upon the adnexa) in which, by his method of treatment, he was able to close the wound and omit drainage, even though there had been a large abscess evacuated. One severe case of appendicitis died; all of the gynecological cases healed by first intention, with the exception of one, in whom a fistula developed; 6 appendicitis cases healed by first intention, 4 developed subcutaneous abscesses, 1 healed by second intention. The special features of his treatment were the application of alcohol-soaked sponges to the abscess cavity, and the dosing of the patient to the limit with quinine.

Quininum bisulphuricum in water, of the strength of 1 to 11, was used, and 3 ccm. of this, equalling about 4 gr., constituted a dose. It was given intramuscularly in the thigh, three doses immediately after operation, three at 4 P.M., three at 10 P.M. For the three succeeding days, three doses were given, three or four times a day, amounting to 36 or 48 gr. a day. After that, the powder was given by mouth. No abscesses developed at site of injection, and the thigh was not painful. Ear-symptoms were usual, and several patients became temporarily deaf. One had amaurosis. [G. G. S.]

2. Perthes presents an interesting study of juvenile arthritis deformans, based on six cases of his personal experience. He considers the condition commoner than is usually supposed, especially as affecting the hip-joint. He believes that bacterial infection is the starting-point of the process, which displays itself as a characteristic deformity of the head of the femur. Limitation of motion, pain, crepitus and limp are the prominent signs. The condition must be differented from coxa vara and tuberculous coxitis. The treatment he recommends is not immobilisation, but systematic passive motion and massage. In advanced cases, with bone changes and deformity, resection of the head of the femur may be indicated.

12. Under the term of "inguinal eventration," the author describes a condition in aged or reduced persons in which muscular atrophy and relaxation allow a visceral protrusion in the groin without the formation of a true hernia. For the relief of this condition he describes and illustrates an operation by which the upper third of the sartorius is transplanted across the inguinal region, its severed distal end being sutured to the rectus. This method, which had been previously suggested by Streissler and Gomoin, gave the writer excellent results in a case which he reports.

16. From a series of experiments in the administration of thyroid preparations, with concomitant study of the blood-picture, the author concludes that such administration causes in a short time an increase of lymphocytes with a simultaneous decrease in the total number of leucocytes at the expense of the polymorphonuclear neutrophiles. He therefore believes that the characteristic lymphocytosis and leucopenia of Basedow's disease is to be regarded as a reaction of the blood-forming organs to an increased thyroid secretion.

26. From a study of intestinal intussusceptions in the ileocecal region, on the basis of a case which he reports, Solieri concludes that, in such invaginations, the individual anatomic disposition of this region is to be regarded not as an etiologic but as a predisposing factor in the production of one or another variety of intussusception. 3. *TABBONI, L. *Central and Peripheral Nervous Lesions of Botulism.* (Preliminary note.)

3. The author describes three distinct types of alimentary intoxication due respectively to infection with Gärtner's bacillus enteritidis, with the paratyphoid bacillus, and with the bacillus botulinus. He discusses the phenomena of botulism and presents clinical and anatomic report of a fatal case. He believes that the manifestations in the nervous system are of toxic origin; that the peripheral nerve lesions are not profound; that the neuritides of botulism are prevailingly interstitial rather than parenchymal or degenerative. [R. M. G.]

## Obituary.

### C. COLE BRADLEY, M.D.

DR. C. COLE BRADLEY, a prominent ophthalmologist of New York City, died at his home in New Rochelle on Dec. 30 from septic endocarditis. He was born in Middletown, N. Y., on Nov. 22, 1862, and was graduated from the College of Physicians and Surgeons, New York, in 1885. For seven years he was in general practice at Fordham, now in the Borough of the Bronx, and he then went abroad for a time to perfect himself in diseases of the eye. Soon after his return he was appointed ophthalmic surgeon to the New York Catholic Protectory, St. Joseph's Orphan Asylum, St. Joseph's Institute for the Deaf, and the Home for Incurables at Fordham. Dr. Bradley was especially well known for his work, in connection with the late Dr. Richard H. Derby, in the examination of the eyes of schoolchildren. In 1886 the New York legislature, in consequence of a report made by a committee of the Academy of Medicine, passed a law requiring that the eyes of children be examined on entrance to institutions, and that cases showing contagious disease should be isolated. It also provided for a monthly examination of all the children in institutions. This was productive of much benefit, but in 1903 Dr. Derby pointed out that 60% of the cases entering the institutions came direct from the public schools, where no recognizance of trachoma was taken. Through the reports of examinations made by Drs. Derby and Bradley public attention was attracted to the prevalence of this disease among the pupils, and for the first time the matter was brought home to the board of health. It is now a matter of record how ably the city health department met the situation. Hospitals were established for the treatment, operative and local, of the affected children, and a permanent system of efficient school inspection by competent inspectors was established.

## Miscellany.

### A DISCUSSION OF LEPROSY.

ON Dec. 29 there was a leprosy field night at the New York Academy of Medicine, the meeting being under the auspices of the Section on Dermatology of the Academy. No less than eleven lepers were presented, and among them were two women. All the patients were brought from institutions: One, a Chinaman, from Paterson, N. J.; four from Brooklyn; two from the City Hospital, Blackwell's Island; three from the New York Skin and Cancer Hospital; and one from the German Hospital. The characteristic features of the cases were demonstrated by Drs. Bronson, Bulkley, Fox, Dade, Fischer, Winfield and Wise. The purpose of exhibiting the lepers was stated to be in furtherance of an effort to educate the public regarding the fancied dangers from this disease and do away with the hysterical attitude it has heretofore shown whenever the presence of a leper became a matter of general knowledge. As a result of this feeling on the part of the public, lepers, in fear and terror, often conceal the fact of their having the disease, instead of applying for and receiving humane and intelligent treatment. The sentiment expressed was for the establishment of national leprosy hospitals in Florida and California, it being urged that it was impracticable for the several states to take action, on account of the small number of cases in each state and the likelihood of one state driving its lepers into other states. Dr. S. Pollitzer gave an historical sketch of leprosy in the United States, showing how the disease had been brought into the South by negro slaves, into San Francisco by Chinese immigrants, and into the old sailing-ship ports of New Bedford and Boston by sailors coming from all parts of the world. At present almost all the recorded cases were to be found in the five seaboard states,—New York, Massachusetts, South Carolina, Florida and California, — and a large proportion

of the cases were in Asiatics and negroes. Dr. Charles W. Duval, of Tulane University, New Orleans, described the long series of experiments he had made in segregating the leprosy bacillus and his final success in propagating the bacilli in a culture medium outside the body, and he expressed the hope that he would eventually be able to work out a curative serum. Dr. Howard Fox read a paper on the "Symptomatology of Leprosy," and Dr. Isadore Dyer, of New Orleans, a paper on the "Sociological Aspects of the Disease and the Question of Segregation," in which he gave some account of what the various nations were doing to control leprosy. Among others who spoke were Drs. Brinkerhoff, formerly of the United States Marine-Hospital Service; White, of Boston; Schamberg, of Philadelphia; Pusey, of Chicago; and Montgomery, of San Francisco.

## MASSACHUSETTS BOARD OF REGISTRATION IN MEDICINE.

The seventeenth annual report of the Board of Registration in Medicine has been issued. For the year ending November, 1911, the board asks for an appropriation which is smaller by $100 than the amount appropriated for 1910. It asks for $4,300 for salaries, $450 for incidentals, $800 for clerical service and $900 for printing, postage and office supplies.

All but one of the 270 persons who applied to the board for registration were examined; 246 of these were school graduates, of whom 202 passed and were registered; 44 were rejected. Of the 23 undergraduates who applied, 6 passed and were registered, 17 being rejected.

The following tabulation gives the average ratings of graduates from medical schools represented by not less than three applicants:

| Medical Institution. | Number Examined. | Average Rating. |
|---|---|---|
| Tufts, | 69 | 76.2 |
| Harvard, | 44 | 78.7 |
| Physicians and Surgeons, Boston, | 23 | 65.7 |
| Massachusetts College of Osteopathy, | 19 | 71.2 |
| Boston University, | 13 | 78.8 |
| Dartmouth, | 10 | 77.8 |
| Foreign, | 10 | 71.8 |
| Baltimore Medical, | 6 | 77.7 |
| University of Maryland, | 6 | 75.6 |
| Maryland Medical, | 5 | 70.9 |

## SEIZURES OF IMPURE FOODS.

Several further seizures of impure food materials in various parts of the United States have been reported during the past week. At Chicago, Ill., the United States deputy marshals raided a car on the Pennsylvania Railroad and seized 6,200 cans containing 124,000 lb. of tomato paste alleged to be "putrid, decomposed and containing filthy matter." This paste was shipped from a firm in Daretown, N. J., to Chicago for use in the preparation of tomato soup at hotels and restaurants. It is stated that the food inspectors found it to contain 500,000,000 bacteria to the cubic centimeter.

At South Boston, Mass., the United States deputy marshal seized last week a consignment of 175 cases each containing three dozen cans of tomato catsup, shipped to Boston from a firm in Mt. Holly, N. J., and alleged to contain decayed vegetable matter.

At Jersey City, N. J., on Dec. 27, 1910, federal officers seized, in the warerooms of a local cold storage company, nine tons of eggs described as "filthy, decomposed and putrid animal matter," and, therefore, held to be unfit for food. These eggs were shipped from Chicago.

## VARIATIONS OF ANNUAL PRECIPITATION IN BOSTON.

During the past fall we have several times referred in the Journal to the drought in Massachusetts and other New England states and the consequent scarcity of water supply in various localities. Advance statistics from the Boston Weather Bureau show that the total precipitation in this city for the year 1910 was only 28.33 inches, a deficiency of 15.05 inches from the normal of 43.38. This is said to be the smallest amount in Boston in any year since 1822, when the precipitation was only 27.2 inches. Moreover, the precipitation in Boston shows a total deficiency of 31.07 inches in the past three years and of 65.52 inches in the past nine years. Certain figures seem to indicate a cyclic or periodic character in the variations of rainfall, since the average amount by decades increased steadily from 1818 to 1868, and has been decreasing steadily ever since. The relation of this question to deforestration is problematical, and can be determined only by further study. It seems likely that the amount of precipitation is also dependent, at least in part, on more subtle and obscure meteorologic and climatic conditions

## Correspondence.

### ORGANIC ARSENIC PREPARATIONS AND "606."

Albany Medical College,
Albany, N. Y., Dec. 28, 1910.

*Mr. Editor:* Erhlich's advocacy of the use of "606" in syphilis has attracted much attention to the various organic arsenic preparations, and many practitioners have suggested the use of the latter as a substitute for the former.

As one of the authors of the only article thus far published [1] which gives an authentic description of the physiologic action of sodium cacodylate based upon pharmacologic investigation and clinical observation, I would esteem it a favor if you would publish a request in your valuable journal that any one who desires information on sodium cacodylate, or any one who has used the drug, successfully or not, communicate with the undersigned.

I am, respectfully yours,
Spencer L. Dawes, M.D.

[1] Dawes and Jackson: Jour. Am. Med. Asso., June 22, 1907, p. 2080.

## PRIZE NOTICE.

THE AMERICAN PROCTOLOGIC SOCIETY'S PRIZE FOR THE BEST ORIGINAL ESSAY ON ANY DISEASE OF THE COLON.—The American Proctologic Society announces through its committee that the cash sum of $100 will be awarded, as soon as possible in 1911, to the author of the best original essay on any disease of the colon in competition for the above prize. Essays must be submitted to the secretary of the committee on or before May 10, 1911, to whom all communications should be addressed. Each essay must be typewritten, designated by a motto or device, and without signature or any other indication of its authorship, and be accompanied by a separate sealed envelope, having on its outside only the motto or device contained on the essay, and within the name, the motto or device used on the essay, and the address of the author. No envelope will be opened except that which accompanies the successful essay. The committee will return the unsuccessful essays, if reclaimed by their writers within six months, provided return postage accompanies the application. The committee reserves the right not to make an award if no essay submitted is considered worthy of the prize. The competition is open to graduates of medicine (not fellows of the Society) and to members of the senior classes of all colleges in the United States or Canada. The object of the prize and competition is to stimulate an increased interest in and knowledge of proctology. The committee shall have full control of awarding the prize and the publication of the prize essay, and it shall be the property of the American Proctologic Society.

DR. LEWIS H. ADLER, JR., *Secretary*,
1610 Arch St., Philadelphia, Pa.

## SOCIETY NOTICES.

THE AMERICAN SOCIETY OF TROPICAL MEDICINE.—The eighth annual meeting of the American Society of Tropical Medicine will be held in New Orleans, on Thursday and Friday, May 18 and 19, 1911.

JOHN M. SWAN, *Secretary*,
Watkins, N. Y.

THE WOMEN'S STATE MEDICAL SOCIETY OF MASSACHUSETTS.—The Women's State Medical Society of Massachusetts in conjunction with the Women's Educational and Industrial Union will hold an open meeting on Preventive Medicine at Perkins Hall, 264 Boylston Street, Tuesday, Jan. 10, 1911, at 8 P.M. Program: 1. "A Few Phases of Women's Work in Continental Cities, with views. Advantages and Disadvantages of Study Abroad," Eliza J. Dadmun, M.D. 2. "Neurasthenic Conditions Occurring in Women after Forty Years of Age," Alice G. Symonds, M.D. 3. "Some Lessons from Child Psychology as Applied to the Training of Children," Edith Hale Swift, M.D. 4. "Hygiene of the Mouth and Air Passages," Isabelle D. Kerr, M.D.

ISABELLE D. KERR, M.D., *Secretary*, 2 Commonwealth Ave.
ELIZA J. DADMUN, M.D., *President*, 483 Beacon St.

## RECENT DEATHS.

HASKINS, FRANK HENRY, M.D., M.M.S.S., died in Springfield, Dec. 30, 1910, aged thirty-nine years.

DR. ALBERT SEESEL, of New York, died at the German Hospital, after a short illness, on Dec. 24. He was a native of Germany, and sixty years of age, and was graduated at Leipsic in 1876.

DR. WILLIS GOSS MACDONALD, an eminent surgeon of Albany, N. Y., died on Dec. 30, from pneumonia. He was born at Cobleskill, Schoharie County, N. Y., on April 11, 1863, and was graduated from the Albany Medical College in 1887. In 1889 and 1890 he pursued a course of surgical study at the University of Berlin and after his return to America was successively appointed instructor in surgery and professor of surgery in the Albany Medical College. At the time of his death he was attending surgeon to the Albany Hospital; the Noble Hospital at Westfield, Mass., and the South End Dispensary. In the Spanish-American War he was surgeon of United States Volunteers, with the rank of major. Dr. Macdonald was one of those most instrumental in securing the establishment of the Raybrook State Hospital for Incipient Tuberculosis in the Adirondacks, and since 1900 he had been a trustee of the institution.

DR. FRANK WHITMAN, who died on Dec. 20, 1910, at Cambridge, Mass., was born in Boston on May 4, 1835. He received the degree of M.D. from the Berkshire Medical College in 1863 and immediately volunteered in the Fifty-Eighth Massachusetts Regiment, with which he served as surgeon through the remainder of the Civil War. He subsequently settled at Bellows Falls, Vt., where he practised medicine until shortly before his death.

DR. ARTHUR B. MUDGE, who died of heart disease on Dec. 26, 1910, in Lynn, Mass., was born in that city on Dec. 14, 1854. He practised dentistry in Lynn for many years. He was a member of the Massachusetts Dental Association.

DR. HORACE S. FULLER, who died of heart disease last week at Hartford, Conn., was born in 1835. During the Civil War he served as an assistant surgeon at Fort Schuyler. He received his medical degree in 1865 from the New York College of Physicians and Surgeons. He subsequently settled at Hartford, and was for many years medical examiner of that city. He had been blind for some time prior to his death.

DR. CHARLES J. CURRAN, who died at North Adams, Mass., on Dec. 30, 1910, was born in South Hadley Falls, Mass. He was educated at Holy Cross College and graduated from the Medical School of the University of New York in 1881. He immediately settled in North Adams, where he had practised medicine ever since. He served from 1881 to 1887 on the local board of health, in 1887 and 1888 as town physician and in 1905 and 1906 as city physician of North Adams. In 1884 he was appointed United States examining surgeon for pensions, and from 1891 to 1896 served as a member of the Massachusetts State Board of Lunacy and Charity. He was a widower and leaves no children.

## ACUTE POLIOMYELOENCEPHALITIS (INFANTILE PARALYSIS).*

BY JOHN LOVETT MORSE, A.M., M.D.,

*Assistant Professor of Pediatrics, Harvard Medical School; Associate Physician at the Children's Hospital and at the Infants' Hospital, Boston.*

My apology for presenting this subject to-night is that Dr. Flexner was unable to accept the invitation of your committee to read a paper on the same subject. I am unable to give you the results of any original investigations of my own, but can only present a summary of our present knowledge of this subject, give a brief survey of the different manifestations of the disease and detail my own opinions as to the proper methods of treatment. Much of what I say will be in quotation marks, and more of it ought to be.

We are justified in stating, on the basis of the work of Flexner and Lewis and others, that acute poliomyeloencephalitis is due to an ultramicroscopic organism. This organism belongs in the class of the filterable viruses in which belong the organism of foot and mouth disease and those of a number of other diseases of animals.

### THE VIRUS.

Filtrates of aqueous emulsions of the spinal cord of human beings or animals dead of this disease are highly potent, 1-1000 ccm. of such a filtrate being sufficient to cause paralysis in monkeys after the usual period of incubation. The virus is very resistant to external agencies and conditions. It withstands glycerinization for weeks or months and drying over caustic potash for weeks. Its virulence is not impaired by freezing for weeks at temperatures from $-2°$ C. to $-4°$ C. It is, however, readily injured by heating, temperatures of from 45° C. to 50° C. for one-half hour rendering it inert. It is readily destroyed by a 1% solution of peroxide of hydrogen and by simple disinfectants such as menthol. It is very questionable whether it has ever been cultivated outside the body, although bouillon inoculated with the virus has become turbid after inoculation. However this may be, paralysis has never been produced by inoculations with any of these possible cultures.

### ANIMAL SUSCEPTIBILITY.

Inoculation experiments have been unsuccessful in all the warm-blooded domestic animals, including chickens and pigeons. This, of course, shows that the epidemic paralytic affections of animals are due to other organisms, and that the disease cannot be contracted from them. Various species of monkeys are, however, very susceptible to infection.

### MODES OF INFECTION.

Infection has been produced experimentally in monkeys by the introduction of the virus intracerebrally, into the peritoneal cavity, into the circulation, subcutaneously, into the spinal canal, into large nerves and through certain mucous surfaces. The introduction of large quantities of the virus into the stomach or duodenum does not lead to paralysis unless the peristalsis is arrested by opium. It must be very seldom that the peristalsis is arrested to the same extent in human beings that it is by opium in monkeys. Infection through the gastro-enteric tract seems, therefore, very improbable. The mucosa of the nasopharynx is more easily traversed by the virus than any other avenue except the brain. If this mucous membrane is lightly scarified and the virus rubbed in, infection occurs promptly. The tracheal mucosa and the lungs do not allow the entrance of the virus unless there are gross lesions, such as would seldom if ever be present in human beings.

### MODES OF ESCAPE.

The virus certainly escapes from the body through the nasopharyngeal mucous membrane. This is proved by the fact that emulsions of the nasopharyngeal mucous membrane of monkeys inoculated intracerebrally with the virus produce the disease in other monkeys. It is not present in the feces, urine, intestinal mucosa or bile.

### CONTAGIOUSNESS.

Acute poliomyeloencephalitis is undoubtedly contagious. It is only necessary to study the history of recent epidemics to be certain of this fact. Further evidence in this connection is the effect of quarantine in limiting the spread of the disease in certain of the recent western epidemics. A study of these same epidemics shows, however, that it is certainly not very contagious. Emerson's figures in his study of the Colrain epidemic of 69 cases show this very plainly. Only two of the patients in this epidemic were isolated during their illness. There were 166 children in the families in which the other 67 cases occurred, only 4 of which developed the disease. There were 4 instances in which the sick child slept with a brother or sister up to the time of the illness, 7 during the first few days of the illness and 5 throughout the entire illness. There were 9 instances in which the other children of the family drank from the same cup, and 12 in which the children in the family and the neighbor's children kissed the sick child during the acute stage. Out of the entire number involved in the intimate contact just described, but 2 developed the disease. Eighty-six other children among neighbors and friends were also in intimate contact with the 67 patients. By intimate contact is meant as free intercourse between the well and sick as the patient's condition would permit. Further evidence that the disease is not very contagious is the fact that it seldom if ever develops in hospitals in which the disease is being treated. No case has ever developed in the wards of the Children's Hospital, although patients with the disease have been treated there for many years. There was a single case in the St. Mary's Infant Asylum in the summer of 1909. In spite of the fact that the

* Read at the joint meeting of the Suffolk District Medical Society and the Boston Medical Library, Nov. 16, 1910.

contact with the other babies and children was very close, no other cases developed.

METHODS OF CONTAGION.

There are no definite data as to how contagion takes place. The fact that it has been proved experimentally that the virus may enter and escape through the nasopharyngeal mucous membrane suggests that this is the usual portal of entry and that the virus is contained in the secretions of the nasopharynx. Further evidence in this direction is the analogy with cerebrospinal meningitis in which the organism is found in the nasopharynx of patients ill with the disease, of convalescents and of persons who have been associated with them. This analogy with cerebrospinal meningitis leads us to believe that acute poliomyeloencephalitis may be transmitted by convalescents, by those who have had the disease in an abortive form and by "carriers."

The facts that epidemics cease with the onset of cold weather and that the virus is resistant to cold suggest an intermediate host which is destroyed by cold, that is, some insect. There is, however, no proof whatever of this supposition. There is no data whatever as to whether the virus may be carried by clothing, fruit or other articles of food. In all probability, however, it cannot be carried in this way.

PERIOD OF INCUBATION.

Experimentally, the period of incubation varies between three and thirty-three days, the average being eight or nine days. Clinically, the period of incubation may be as short as twenty-four hours. It is impossible to state how long it may be, because it is probable that if the organism enters through the nasopharynx it may remain latent in the nasopharynx for days or weeks, as is the case in diphtheria and probably in cerebrospinal meningitis. Since the period of incubation is unknown, it is impossible to state how long the period of observation should be. Roughly, it may, perhaps, be placed at three weeks.

PROTECTION AGAINST CONTAGION.

There is no question but that patients with acute poliomyeloencephalitis should be quarantined in much the same way as those with scarlet fever and diphtheria. The only question is how long this quarantine should be. At the present time we have no data on this point. I have personally adopted three weeks as the period of quarantine. It may be, however, that three days is long enough, or it may be that three months is necessary. It would be of great advantage if the State Board of Health would set some definite time, even if this time is wrong and has to be changed later. Other questions which immediately arise are whether the other children in the family shall be allowed to mix with their playmates and attend school, and whether the attendants and other members of the family shall be quarantined. At present it seems wise to keep the other children of the family out of school for a number of weeks. It is hardly possible, however, to compel the adult members of the family to give up their work and pleasure.

It is possible that hexamethylenamin may prevent the escape of the organism from the body. It seems wise, therefore, to give it to patients during the acute stage. It is also possible that it may hinder or prevent the development of the organisms in persons exposed to the disease. It seems reasonable, therefore, to give this drug to those who are exposed.

Since peroxide of hydrogen destroys the organism, and since the organism is undoubtedly present in the nasopharynx in some if not in all cases, it seems rational to spray the nasopharynx of patients with weak solutions of peroxide of hydrogen in order to diminish the chances of the infection of others. Since the virus may enter through the nasopharyngeal mucous membrane, it seems reasonable to attempt to prevent such entrance by using peroxide of hydrogen in the nose and throat of those who have been exposed to the disease. It must be remembered in this connection, however, that peroxide of hydrogen is an irritant to the nasopharyngeal mucous membrane of many people, and in such people it might further increase the danger of infection.

A second attack of the disease is extremely rare in the same individual. Reinfection is impossible experimentally. Active immunity has been produced in animals. "At present, however, the experimental basis is entirely inadequate to justify the attempt to induce active immunity as a protective measure in human beings."

The only general advice which it is safe to give at present to those who ask what they shall do to prevent their children from contracting the disease is that they should not deliberately go to a place where there is infantile paralysis and that, if they are in such a place, they should, as far as possible, keep their children away from other people. In individual instances it may be wiser to take children away from localities in which the disease is prevalent. The danger of infection is, however, hardly great enough to warrant such advice to a community as a whole. There is no question but that acute poliomyeloencephalitis is one of the most terrible of diseases, in that it is not only frequently fatal but especially in that a large proportion of those who do not die are left more or less paralyzed for life. The importance of the disease has, nevertheless, been greatly exaggerated within the last few years, probably partly because of the increased prevalence of the disease, but largely because of the newspaper notoriety which it has received. The largest epidemic which has ever occurred in Boston was in 1909. There were 299 cases in Boston in that year, 20 of which died, giving a mortality of 7%. There were 107 cases of tubercular meningitis reported during the same year, all of which died. Tubercular meningitis, like other forms of tuberculosis, is preventable! During this period there were 2,095 cases of scarlet fever, 82, or 3.9% of which died, 2,720 cases of diphtheria, 193, or 7.1% which died, and 666 cases of typhoid fever, of which 91, or 13.6%, died. No one seems to be

especially worried about these diseases, however, and the newspapers are not filled with accounts of them!

PATHOLOGY.

"Wherever the virus enters it has a predilection for the nervous system. The first lesion is a leptomeningitis. Cellular infiltrative changes are set up which are most marked in the perivascular lymph spaces of the arteries entering the nervous tissues. The vascular lesions constitute the primary causes of the lesions of the nervous tissue, the severity of which is determined by the particular vessels affected and the intensity of the involvement." Secondary lesions occur in the intima which result in edema and hemorrhage. The anterior horns are most affected because the arteries are larger; the lumbar and cervical enlargements, because the blood supply is more abundant. All parts of the central nervous system may be involved, both the gray and the white matter. The peripheral nerves show parenchymatous degeneration. "In the severe or fatal cases the entire cord with its pia mater, the entire medulla oblongata and pons, the basal ganglia and often the cortex of the brain are involved, the degree of the involvement varying in different instances. In the mild cases the process is much more extensive than was formerly supposed. All gradations between the mild, serious and fatal cases are found pathologically." It is evident, therefore, that our conception of the disease must be enlarged to include the acute polioencephalitides, both cortical and basal, and the poliomyelitides as well as many transitional forms. A better term for the disease than infantile paralysis or acute poliomyelitis is, therefore, acute poliomyeloencephalitis.

SYMPTOMATOLOGY.

If we think of the disease as a poliomyeloencephalitis with meningeal complications and appreciate the fact that the disease may affect any or all parts of the gray matter of the central nervous system, and in all possible combinations, we shall understand better the innumerable manifestations of the disease and be less likely to overlook it or mistake it for some other condition. We must never forget how variable the symptoms may be. If we are awake to all the possibilities, we are not likely to overlook it. The best classification of the various manifestations of the disease is that of Wickman.

*Wickman's Classification.*

1. Ordinary spinal paralysis; anterior poliomyelitis.
2. Progressive paralysis, usually ascending, less often descending; Landry's paralysis.
3. Bulbar paralysis; polioencephalitis of pons.
4. Acute encephalitis, giving spastic mono- or hemiplegia.
5. Ataxic form.
6. Polyneuritic; multiple neuritic type.
7. Meningitic form.
8. Abortive form.

*Ordinary form.* — It is hardly necessary to take up the ordinary spinal form of paralysis, with which you are all familiar. It must be remembered in this connection, however, that the paralysis may involve only single muscles, such as those of the neck, abdomen or back. Incidentally, when the abdominal and back muscles are involved, the prognosis is very good.

*Progressive type.* — The following history is a good example of the progressive type.

A boy, ten years old, began to complain of pain in the legs Aug. 18 and by night was unable to walk without help. Pain and loss of power were rather more marked on the 19th. A physician who was called found a temperature of 102° F. and made a diagnosis of rheumatism. The pain and fever continued. Pain and loss of power appeared in the arms Aug. 21. The morning of the 22d he began to have difficulty in breathing and to have what were supposed to be convulsions. He rapidly became unconscious. Micturition and defecation were both involuntary.

He was moderately cyanotic. Respiration was short and gasping, but not very rapid. Frothy mucus ran from the mouth occasionally or was spit up with considerable difficulty. He was entirely unconscious. There was occasional twitching of the face. There was no rigidity of the neck. The pupils were equal and reacted to light. The chest was fully expanded and immobile; it was tympanitic on percussion. The abdomen was moderately distended and tympanitic. The diaphragm moved, but the excursion was very slight. There was a complete flaccid paralysis of all the extremities. The knee-jerks were absent. Kernig's and Babinski's signs were also absent. He died a few hours later.

*Bulbar type.* — The following cases are good examples of this type. The first belongs in the class which has in the past been called polioencephalitis superior, and the second in the class which has been called polioencephalitis inferior.

A boy, five years old, seemed a little out of sorts Aug. 16. The next day, while walking along the street, he felt weak, leaned against a fence and vomited. He then walked a short distance, sat down in a chair on the piazza and slept for half an hour. On waking he was unable to walk because of staggering. The eyes were turned upward and remained in this position until the next day. He talked and seemed rational. He had no paralysis of the face or extremities. He twitched a good deal for several days and had cold sweats. The staggering gait lasted about a week. He complained at times of double vision. Strabismus was noticed about Sept. 1. He was seen Sept. 19.

Physical examination was entirely negative except for complete paralysis of the left external rectus and partial paralysis of the right. The pupils were equal and reacted to light. The optic disks were normal.

A boy of five was taken suddenly sick with fever and vomiting July 26. The vomiting and fever continued. He began to have difficulty in swallowing the morning of the 28th and his voice became a little hoarse. When seen at 4 P.M. he

talked in a whisper and apparently had some trouble in swallowing. Examination of the mouth and throat, however, showed nothing abnormal. The neck was held rather stiffly. Nothing else was detected by a very careful general examination. The next day he was unable to swallow anything, even his saliva. When seen at 9 P.M. the whole of the right side of the face, including the forehead, was paralyzed. The tongue was protruded in the median line. The uvula could not be elevated. The pupils were equal and reacted to light. There was no strabismus and no stiffness of the neck. There was a complete paralysis of the extensor muscles of the right arm. The left arm and the legs were normal. The knee-jerks were present.

*Acute encephalitic type.* — The following case is a good example of this type and shows how difficult the diagnosis is in this class of cases, which is more often than the others confused with tubercular meningitis.

A boy, three years old, fell down stairs, striking his head, early in the morning of Aug. 3. He was apparently not hurt and appeared well all day. He began to vomit during the morning of Aug. 4 and continued to vomit at intervals of about an hour until 3 A.M., Aug. 5. He did not vomit again. There had been no known indiscretion in diet and the bowels were open. He was delirious in the early morning. He was seen at 2 P.M., Aug. 5.

He was restless and irrational, but when roused noticed a little. There was no rigidity of the neck and no neck-sign. The pupils were equal and reacted to light. There was no spasm or paralysis. The knee-jerks were equal and normal. The Kernig and Babinski signs were absent and there was no ankle clonus. The temperature was 99.8° F., the pulse 120, the respiration 36. The rest of the physical examination and the urine showed nothing abnormal.

The fluid obtained by lumbar puncture was under considerable pressure. It was at first clear and then somewhat blood stained. No fibrin clot formed in twenty-four hours. It contained 360 cells to the cubic millimeter, a part of which were undoubtedly due to the admixture of blood. The differential count of these cells, which showed 90% of mononuclears and 10% of polynuclears, shows that only a few of them came from the blood, because if many of them had come from the blood the number of polynuclear cells would have at least equalled that of the mononuclears. No tubercle bacilli or other organisms were seen in a routine examination, and cultures were sterile.

He passed a very restless night and at times was quite noisy, requiring morphia to keep him quiet. He was quiet and drowsy during the morning of Aug. 6. There was no rigidity of the neck or neck-sign. The pupils were equal and reacted to light. The knee-jerks were equal and lively, the abdominal and cremasteric reflexes normal. There was no Kernig's sign or clonus.

He was quiet Aug. 7. There was slight rigidity of the neck. The pupils were equal and reacted to light. The knee-jerks were present but sluggish. There was a suggestion of Kernig's sign on the left, but none on the right. The Babinski phenomenon was absent.

Improvement was steady and uninterrupted from this time on.

*Polyneuritic type.* — The polyneuritic type, understanding by this term the type in which there are pains in the extremities, is very common. The pains are sometimes in the joints, more often along nerve trunks or indefinite in their distribution. They are usually most marked in the paralyzed parts. In a few instances I have found tenderness over the nerve trunks. Pain and tenderness have in several instances been so severe as to cause the attending physician to make a diagnosis of rheumatism and to entirely overlook the paralysis. On account of the pain on motion the extremities are often held rigidly and all motions as vigorously resisted as possible. This combination of rigidity and resistance is possible, of course, only when the muscles are but partially paralyzed or when some of them are intact. The failure to appreciate the significance of this condition of combined flaccidity and spasticity has led, in my experience, to many errors in diagnosis during the acute stage.

*Meningitic type.* — The following case is a good example of this type, which is often confused with cerebrospinal meningitis. This patient was, in fact, shown by one of the instructors in the medical school as a case of cerebrospinal meningitis.

A girl, three and one-half years old, was taken suddenly sick Sept. 5 with a high fever. She was very irritable and complained of pains all over, but especially in the head and back. She cried out when touched and lay with her back arched and head drawn back. She had not vomited. The bowels were constipated. She passed urine normally. She was seen Sept. 9.

She was irrational and very irritable, crying out sharply when disturbed. The ears were normal. The pupils were equal and reacted to light. The eyes were kept closed and there was a moderate amount of photophobia. The neck was rigid and apparently tender. The spasm, however, seemed to be partly voluntary. The back was arched and rigid, but the spasm here also seemed to be partly voluntary. She did not use her right arm. The hand was clenched with the thumb inside. She did not move her left leg at all, but moved the right slightly at the hip. The extremities were somewhat rigid and passive motions caused much pain. The knee-jerks were absent. Kernig's and Babinski's signs were absent. There was no disturbance of sensation.

*Abortive type.* — It is very difficult to give illustrative cases of the abortive type because, if there is no paralysis, it is impossible to prove that they are cases of poliomyeloencephalitis. Such instances as the following show how indefinite this type may be. There were eight children of about the same age in a small summer colony at the seashore. All of them had an acute gastro-intestinal disturbance with slight fever lasting four or five days. One of them was found, a week later, to have a slight paralysis of both legs and one arm. He undoubtedly had acute poliomyelo-

encephalitis. It is fair to assume that the others had it also in an abortive form which did not result in paralysis.

A good deal has been written recently about a triad of early symptoms, sweating, irritability and hyperesthesia. I have seen all of these symptoms, singly or in combination, in the early stages of this disease, but my experience leads me to believe that they are not at all constant. If they are present, they are strong evidence in favor of this disease, but their absence does not count against it. The hyperesthesia is the most constant and the most important of the three.

*Leucocytosis.* — There is a considerable amount of scattered data as to the leucocyte count in acute poliomyeloencephalitis. Some observers have found a diminution in the number of cells, others a considerable increase, others have obtained no constant results. Lucas, in his experimental work with monkeys, found that there was always a marked drop in the number of white cells during the acute stage, the lowest count being on the second day after the appearance of the paralysis, the diminution in some cases being as much as 50%. There was also a lymphocytosis during the acute stage. He found little or no increase in the number of white cells in four cases in children, but a decided lymphocytosis.

My own experience is limited. I have never found a diminution in the number of white cells, but usually an increase, in some cases as high as 34,000. I have made no differential counts.

*Spinal fluid.* — Experimentally, there is an increase in the number of white cells during the stage of incubation, the majority of the cells being mononuclear, some of them polynuclear. There is a greater increase during the prodromal stage, the proportion of mononuclear cells being still greater, while during the early acute stage there is a very marked increase in the number of cells, all of the cells being mononuclear. The fluid shows a fibrin clot. At the end of from seven to ten days very few cells are left, some of which are again polynuclear. Clinically, the fluid is often under increased pressure during the early stage, is always clear and in most instances contains a fibrin clot. It contains an excess of cells which are practically all lymphocytes. In my cases the number of cells has varied between 75 and 360 to the cubic millimeter. The fibrin clot soon disappears, the cells diminish in number, the proportion of large mononuclear cells increases and finally some polynuclear cells appear. I have found an excess of cells in the cerebrospinal fluid as late as the twentieth day.

## DIAGNOSIS.

It must be admitted that the diagnosis of acute poliomyeloencephalitis is at present impossible before the appearance of the paralysis. We may suspect it, however, in times of epidemics. There is nothing constant about the early symptoms, which in some instances are like those of ordinary gastro-intestinal disturbances, in others like those of colds and sore throats, and in others entirely indefinite. The only way in which, with our present knowledge, we can make the diagnosis in every instance before the appearance of the paralysis is to say that every sick child we see during the summer may be developing infantile paralysis. The triad of symptoms already mentioned is not at all constant. The hyperesthesia is the most important. The number of white corpuscles is so variable that the leucocyte count is of but little value in differential diagnosis, although a hypoleucocytosis points somewhat toward poliomyeloencephalitis. If further investigations show that there is a relative lymphocytosis in the early stages, this point will probably be of considerable importance.

It is almost certain that the diagnosis can be made in the early stages of the disease before the appearance of the paralysis from the examination of the fluid obtained by lumbar puncture. In order to make such early diagnoses, however, it would be necessary to do lumbar punctures on every sick child during the summer, since there is nothing about the early symptoms to distinguish the onset of poliomyeloencephalitis from that of any other disease. This hardly seems a rational procedure. In many instances, moreover, it is impossible from the examination of the cerebrospinal fluid to make a diagnosis between tubercular meningitis and poliomyeloencephalitis, since in both instances the fluid may be clear and the number of cells not greatly increased. The great majority of the cells in both are, moreover, lymphocytes. The finding of tubercle bacilli in the fluid is, of course, proof that the condition is tubercular meningitis. Tubercle bacilli are, however, not found in more than 10% of the cases of tubercular meningitis unless the examination is much more careful than the usual routine one. The fluid in cerebrospinal meningitis is materially different, being turbid or purulent and containing a great many cells, the majority of which are polynuclear, and usually many organisms.

Finally, we are sure to miss the abortive cases.

## PROGNOSIS.

The prognosis as to life depends, of course, on the nature of the individual case. It is practically hopeless in the lower bulbar type and in the progressive type when the muscles of respiration are involved. It is impossible to give a general prognosis as to life. Statistics on this point are all unreliable because only the cases with paralysis are included. The abortive cases are overlooked and many of the fatal encephalitic cases are unrecognized.

It is impossible to give an accurate prognosis early in the disease as to how complete the recovery from the paralysis will be. The paralysis may entirely disappear in the most marked cases and, on the other hand, may improve but little when the original paralysis is slight. In general, it is safe to promise that the final paralysis will be much less than the initial, that in all probability some paralysis will remain, that but little improve-

ment will occur after the first six months and none after the first year.

TREATMENT.

The prophylactic treatment has already been considered.

Hexamethylenamin can do no good after the appearance of the paralysis, because the harm has then already been done. It is possible, perhaps probable, that it may do good if it is given before the appearance of the paralysis. It certainly should be given to all children who may possibly have been exposed to the disease. Since there is nothing characteristic about the early symptoms of acute poliomyeloencephalitis, it would be necessary, in order to give it in time, and in order not to miss any of the cases, to give it to every sick child all summer, which certainly does not seem reasonable.

Local applications are useless. It is unreasonable to expect any application on the outside of the body to affect a micro-organism in the inside of the spinal canal. It is also unreasonable to expect to diminish the congestion in the spinal cord by applications externally, because, in the first place, there is no direct communication between the circulation on the outside of the body and that of the spinal cord, and because, in the second place, the congestion is not due to an increased supply of blood, but to a blocking of the arteries from an infiltration of cells on the outside of the vessels. The only effect which outside applications have is to make the patient uncomfortable.

The use of the affected parts, electricity and massage must be avoided during the acute stage, because stimulation of the peripheral ends of the lower motor neurons causes stimulation of the ganglion cells of the neurons and consequently tends to increase the trouble. It is rest and not stimulation which the ganglion cells need. These measures should not be begun until six weeks after the onset of the paralysis. If there is pain or tenderness, they should not be begun until three weeks after the cessation of the pain and tenderness, however long this may be.

Strychnia must be avoided in the acute stage because it is a stimulant to the lower motor neurons and, as already stated, it is rest and not stimulation which is needed.

Flexner states that "the serum treatment of poliomyelitis must at the present time be regarded as strictly in the experimental state, and it cannot be predicted how soon or whether ever at all such a form of the specific treatment of the disease will be applicable to the spontaneous epidemic disease in human beings."

It is probable that on general principles moderate catharsis and a light diet are of some use in limiting the progress of the disease.

A very important part of the treatment during the acute stage is that directed to the prevention of contractures. These develop very quickly and, if they develop, make the later treatment much more difficult and materially delay recovery. The development of contractures can easily be prevented by using a cradle to keep the weight of the bedclothes off of the legs and by the proper application of light splints.

I will leave the later treatment of these cases to the gentlemen who follow me, as they are far more competent than I am to speak of it.

## THE TREATMENT OF ACUTE POLIOMYELITIS.*

BY W. E. PAUL, M.D., BOSTON.

AN intelligent conception of treatment requires a clear idea of the one essential structure in which is the lesion responsible for nearly all the poliomyelitic wreckage. That one structure is the anterior cornual cell and its peripheral prolongation, the lower motor neuron. The preservation and restoration of this unit is vital.

The care of poliomyelitis may be divided into three stages: First, that of the acute illness; second, that of the convalescence; third, that of the permanently damaged neuromuscular structures.

The period of acute illness extends through the time of constitutional disturbance and merges into the convalescent period with the cessation of fever and the diminution of pain. Van Gieson's conception of cytolysis, cytoclasis and cytothesis applies notably to the pathological course of poliomyelitis. A nerve structure, such as a cornual cell, may be hurt in varying degree up to the limit beyond which restoration in any measure is impossible. This injury between the limits of some measure of recovery is denominated cytolysis; the destruction of a cell is cytoclasis; the building up of a damaged cell is cytothesis.

The earliest treatment of the acute stage has been described by Dr. Morse and is directed to attempts to lessen the cytolysis or the effects of the infection.

Practically no dissent exists regarding the importance of one measure uniformly to be carried out during the acute period. This measure is rest as complete functionally and bodily as can be maintained in bed. Though hard for the parents to see nothing being done for the paralysis, it is probably true that cytothetic process in the parts vitally necessary for functional restoration is most beneficently favored by rest. If the nerve structures affected by the infection are not restored, it is a simple corollary that the muscles over which they preside are beyond help from medical art. Primarily, then, in the acute stage the therapeutic aim is to lessen and arrest the processes of cytolysis.

In the early convalescent period a tendency to contracture not infrequently develops, at the elbow, shoulder, ankle or knee. The weight of the bedclothes on the feet is especially insidious in producing equinus positions. A frame supports the bedclothes over the feet, and strapping and light splinting may be required, or perhaps a Gower's boot applied. As a rule the continuance

*Presented at the Boston Medical Library meeting in conjunction with that of the Medical Section of the Suffolk District Medical Society, Nov. 16, 1910.

of pain prohibits active measures and requires that quiet and rest be continued. The average period of rest would be four to six weeks. Fresh air, good nutritive measures and keeping up the patient's spirits are helpful. Special pains should be taken to keep a cold extremity warm.

The time for active treatment has now arrived and a multitude of measures could be enumerated which at times might be of some use. The healing forces of nature are the vital factors. If she restores the central nerve structures we can hardly thwart her measure of cure, and our therapeutic attempts are at best her feeble aids. It is true, however, that a small functional gain rewards the effort and gives a good indorsement to the means by which it is attained.

The chief measures of treatment in the convalescent stage are electricity, exercises active and passive, and massage.

Perhaps no measure of treatment has received more estimates of its value than electricity, and it is not strange when it is regarded from some points of view. If the amount of useless, routine, electricity that has been given in poliomyelitis without definite purpose influences the judgment of its value, one is led to say all electrical treatment is without effect. Naturally it is difficult for a conscientious physician who uses electricity rarely and empirically to be at all satisfied with such therapy.

Again, if one considers that some muscles remain powerless after electrical treatment, he is led to condemn electricity as it fails where it is most essential to attain a cure.

Electricity is further condemned because some young children react to the sensations from an electric current by crying, becoming unmanageable and getting nervous. Such conditions are partly due to lack of tact. In most children it is possible to give electrical treatment if the initial séances are carefully managed.

The chief influence against a fair judgment of the value of electricity comes from a misapprehension of the indications for its application as well as from lack of instruction and training in the use of this remedial means. Hardly a single article on treatment with electricity describes accurately or definitely electrical therapy as applied to degenerated nerves. It is this that leads to so much that is futile in giving electricity, and most of such therapy could easily be called meddlesome.

What is aimed at in the use of electricity? Exercising a muscle that can in no other way be made to contract, or which is weak in function. This gives great value to electricity as it makes a muscle come nearer functioning than is possible by other means. On closing the current a contraction occurs in a portion of the muscle and this can be repeated as many times as desired. The different portions of a muscle are thus exercised, though the muscular response is far below that obtained in a healthy muscle. If a muscle is thus exercised it seems probable that it will be in better condition to take up function when the regenerated nerve supplying it resumes functional conductivity than would be the case if exercising by electrical stimulation had been omitted.

Should a nurse or the doctor give electricity? The best results can be obtained only by skillful applications. Rarely is a nurse trained to secure muscle reactions with properly selected currents and poles. The physician trained in the use of electrical apparatus is the one who should do such work.

In poliomyelitic paralyses there exists in varying degree the electrical muscle reactions accompanying degeneration of nerves. The chief electrical feature is that there ceases to be any response through the nerves to faradism or galvanism. The only response obtainable is by direct stimulation of the muscle itself, and the only current that can stimulate the muscle is the galvanic. Galvanism is, therefore, to be chosen in the electrical treatment of the paralyses. Unless the higher and more complete degrees of paralysis exist, the muscle will react better to the negative pole; that is, it will react with less current and with more muscular power. The reaction of degeneration which is thus used in treatment consists of a slow progressive contraction of part of the muscle as contrasted with the quick response of most of a muscle in normal reactions.

The faradic current is efficient if the muscle is weakened but not paralyzed and a contraction of the muscle can be obtained by stimulation through the nerve supply or at the motor point. In such muscles a fair degree of voluntary muscular power is retained and functional use is more potent as a remedial measure than electricity.

But the important use of electricity is the application of the galvanic current in cases of paralysis in which there is no voluntary movement in the muscle and no muscular response through electrical stimulation of the nerve supply. In these cases if the degeneration of the nerve is complete enough to give a better response to the positive pole, then the positive pole should be used to stimulate the muscle in treatment; if a less degree of degeneration is evidenced by better response to the negative pole, then the negative pole is the one to apply directly to the muscle in treatment. Daily or triweekly applications are advisable. Thirty to fifty times at one sitting is a good number of times to exercise a muscle with the galvanic pole selected. The indifferent pole should be placed at different sites each time; one day it may be applied to the nape of the neck, another over the sternum, etc.

If no contraction can be obtained by galvanism, the current may be applied over the muscle on the assumption that sensory stimuli reach the motor arc with some influence for good. The negative pole should be used over the muscle in this method.

Applied to the spine electricity is probably valueless.

To go into the detail of electrodes, electrophores and batteries would require too much time.

Exercises are prescribed for the weakened muscles which preserve some voluntary power.

They should be given under the nurse's or mother's direction if the child is able to follow directions or imitate the instructor. Each movement should be made three to five times at first and later the number of times increased; resistance may be made to the movements. Dr. John Ridlon tersely states that "active movements performed by the patient himself have positive curative value, probably greater than any other remedy."

Passive movements preserve the normal range of a joint and help prevent contracture.

Ingenious adaptations may be made of toys and playthings, as, for instance, squeezing a rubber ball or automobile horn, using a dynamometer, using a bow and arrow, the return ball, drumming, kicking football, etc. The Zander machines are valuable and can more definitely determine a special exercise than other methods.

Massage should be begun early in the active treatment a month or six weeks after the onset of the disease. At first gently rubbing is enough, but in two or three weeks kneading can be added. The massage should not cause pain and in the neuritic form will of necessity be of very mild degree in the earlier weeks. Massage stimulates and maintains nutrition.

The average case will be getting about a little in the sixth week and within two months is out of doors. With good spirits the child is using his unaffected muscles actively and gaining by strides in the power of his weakened muscles, while the more severely damaged show slight change, and those hopelessly paralyzed progressively atrophy.

If an attempt is made to formulate statements of the relative values of electricity, exercises and massage, one must also classify the cases to which these measures may be applied. If we divide the paralyses of poliomyelitis into three classes, varying only in degree, at once we have a better basis for determining measures to be used or rather, perhaps, for summing up the value of those employed up to the time of recovery, or the time progress toward recovery ceases.

First are the cases with weakened muscles, and in this class the order of value in treatment is (1) Voluntary exercises, (2) electricity, (3) massage.

Second are the cases with paralysis, moderate atrophy and reaction of degeneration; in this class the order of value in treatment is (1) Electricity, (2) massage, (3) passive exercises.

Third are the cases with absolute paralysis, complete reaction of degeneration, extreme atrophy and cold extremity; in this class of case the order of value in treatment is (1) Massage, (2) passive exercises, (3) electricity.

In the treatment of the paralyses the goal is to save the motor neurons from damage; if damaged, to restore these neurons to health partially, if possible completely; if the neurons are destroyed, to make up the loss by ingenious adjustment and mechanism. All these efforts are to save, restore and supply functional use.

These measures may be kept up with benefit for a year or more, as the limit of improvement which is a part of the recovery from the disease ceases probably inside of two years from the onset.

With the cessation of improvement there is the condition of permanent crippling to be considered. Much help can be extended to the patient by the orthopedist. Apparatus ingeniously contrived can improve the patient's walk; operations benefiting relaxed ligaments may lessen the separation of joints; arthrodetic operations and tendon and nerve transplantations may partially restore functioning powers to members severely crippled.

The disordered nutrition accompanying the paralysis in poliomyelitis renders the recovery and results from operative procedure less sure than in the operations on healthy bones, muscles and tendons.

In conclusion, let me call attention to the fact that wide as is the range of pathological damage to nerve structures in poliomyelitis, it is in only one group of neurons that the harm done calls for therapeutic measures during convalescence and the later stages of the disease. The meninges, the sensory columns, perchance, every columnar tract of the cord, the peripheral nerves, may all be involved as well as the anterior cornual cells and higher motor nuclei, but treatment has to be considered in a practical way only in the conservation of these motor neurons.

### DISCUSSION.

DR. R. W. LOVETT called attention to the fact that epidemic infantile paralysis was not altogether new in this community, but that in 1904 there was an epidemic of 136 cases in Rutland, Vt., which did not spread throughout the country. He had, therefore, looked into certain general conditions as possibly accounting for the increased spread. Occurrence of a great epidemic in Norway and Sweden in 1905, followed by the large epidemic in New York in 1907 and the epidemics in Massachusetts, Kansas, Nebraska and Minnesota in 1909, suggested that possibly the disease was brought to this country by immigrants.

The total immigration to this country rose between 1904 and 1907, after which it dropped, but Scandinavian immigration dropped in 1905, 1906 and 1907 from the figures of preceding years, and in 1907 — the year of the New York epidemic — there were a smaller number of Scandinavian immigrants than since 1901.

Considering other factors of possible importance, — in 1904 the railroads were carrying 46 passengers per train mile, and in 1908 they were carrying 54 passengers per train mile, but the increase was even more marked in electric railway travel, the number of passengers carried increasing between 1902 and 1907 by 4,000,000,000. Automobile traffic also has increased very much. In 1905 there were 4,800 automobiles registered in Massachusetts, and in 1909 there were 24,000 registered; that is, in the period between these years, the number of automobiles in this state increased five times. It is, therefore, evident that travel is very much more common now than it has been in preceding years.

An investigation into the amount of fruit used

was not significant. With regard to the question of dust, although on the Massachusetts coast the rainfall was much less in the last five years than it was in the five-year period ending in 1904, the rainfall in the West in the last five-year period was greater than that in the preceding period, and in New York the rainfall is the same in the two five-year periods.

The State Board of Health intends in the near future to take up the question of the prevalence of insects in relation to the spread of the disease.

The disease as it has occurred in Massachusetts has now been under observation by the State Board of Health for four years, and there are one or two matters that may be of interest. The disease on the whole has affected river valleys more than the coast towns. Although it has been stated by writers on the subject that localities severely affected one year were likely to be immune in the following year, from the experience in Massachusetts this can only be applied to small communities. If a large territory like a state is considered, increased prevalence of the disease in one year is followed by a diminished prevalence in the next year, but not by immunity. A town or city, however, severely affected one year is practically immune the next, as shown by the number of cases in Boston, where there were 299 cases in 1909, and a report of only 11 in the first eleven months of 1910.

The disease seems to occur unaccountably both in communities which have been immune previously and in communities which have been moderately infected. There were two epidemics in 1910, one in Springfield, which had had almost no cases up to this time, and one in Fall River, which had shown each year a few cases of the disease. The part of the state that has suffered least is a part running north and south the whole depth of the state, beginning a few miles east of the Connecticut River and ending east in a line running north and south about through Concord, Mass.

The transmissibility of the disease is admitted by all modern writers on the subject, and in Massachusetts there have been many instances of what have appeared to be direct transmission and of transmission by a third person.

Dr. Rotch said that to be especially noted in our present knowledge of the disease is that the primary lesions are much more diffuse than was formerly supposed, including the meninges, the white and gray matter of the cord, both sensory and motor tracts, the pons, medulla, the central nerve centers and the brain axis. The number of clinical varieties is also much greater than was formerly supposed. The disease seems to be comparatively new as there is no record of it previous to 1843. The diagnosis of the disease in its early stages is of importance, and the study which Dr. Lucas has been making in regard to this is noteworthy as showing what probably will eventually be accomplished in this direction. The early diagnosis will probably be shown to be much aided by an examination of the blood and also of the spinal fluid. A diminished white count has been found early in the disease as in contradistinction from the usual leucocytosis of an acute infection. The spinal fluid usually shows an increase in amount and a marked cellular increase due to mononuclear infiltration. These conditions decrease rapidly as paralysis appears. Lumbar puncture is indicated, especially in the beginning, in that it relieves pressure and draws off a considerable portion of the infecting material.

## A REVIEW OF SANITATION IN PANAMA.*

BY FRANCIS P. MC CARTHY, M.D.,
*Resident Physician, Boston Consumptives' Hospital.*

For many years the Isthmus of Panama has held the reputation of being one of the most unhealthful places in the world. Diseases like yellow fever and pernicious malarial fever have been endemic for centuries, with occasional outbreaks of bubonic plague and smallpox, and, together with the omnipresent amebic dysentery, its reputation as a community with the highest death-rate in the world has been justified. The enervating, hot, damp climate has had considerable influence in bringing about and perpetuating the unhealthful conditions, but there is one more potent factor which has kept up these conditions, and that is the constant non-immune population, which has been relatively more numerous in Panama than in any other tropical country.

Yellow fever, which, up to the American occupation, has reaped a grim harvest for centuries, was especially fatal to any newcomers, particularly in the French construction days. The native population have no fear of this disease on account of their acquired immunity from having the disease in a mild form in childhood. The disease has lost its grip at intervals for want of a non-immune population to feed upon, only to break out with renewed vigor with each influx of foreigners to the mosquito-infested zone. No human hand was raised to stem the ravages of this disease, as no one knew the method of dissemination of the dreadful scourge.

Situated about 9° above the Equator, Panama is in the tropical belt. The rainfall is one of the heaviest in the world, differing markedly on the opposite sides of the Isthmus. The rainfall on the Pacific side is about 72 inches per year, while on the Atlantic about 130 inches per year. This difference is due to a high range of hills which cross the Isthmus at Culebra and act as a watershed. Last year in Colon, the rainfall totalled 244 inches, the heaviest recorded in the Isthmus, and probably the heaviest in the world. Over 40 inches fell during the month of November alone. The temperature averages during the day about 80 to 90°, rarely going above 90° in the shade, although in the sun it ranges as high as 120 to 130°; however at night there is a decided drop, the temperature averaging between 66 and 70° from sunset to sunrise. The humidity is relatively very high, averaging almost 90%, and this constant high humidity, together with the high temperature, makes the climate of the Isthmus so enervating.

* Read before the Norfolk District Medical Society, Oct. 25, 1910.

On account of the extreme dampness everywhere present, clothing becomes mildewed over night, and foods quickly perish unless kept in dry places. The discovery of gold in California, and the lack of a safe and rapid transcontinental route of getting to the scene of operations, induced many thousands of treasure hunters to attempt the Isthmian transit. During the seven and eight years succeeding the discovery of gold, it is estimated that twenty-five thousand passengers annually crossed the Isthmus on pack mule trains. The mortality from disease among these travelers, considering the few miles traversed, was appalling, and to-day we have mute testimony in the number of graveyards scattered along the line of the Panama railroad.

About this period the construction of the Panama railroad was under way, from 1851 to 1855, and after those four years of the most heroic work the road was completed, but at a tremendous sacrifice of human life. Many interruptions occurred during these years, chiefly due to wholesale desertions among the laborers, who comprised West and East Indians, Chinese, Europeans and Americans, as a result of the inroads of the Isthmian fevers among the men. One often hears the remark that there was a life sacrificed for every tie across the Isthmus. During the French régime from 1883 up to the time the Americans took possession the unsanitary condition of the Isthmus of Panama is well shown by the awful death toll among the heroic workers of those days. The one obstacle which contributed more to the failure of the French in the construction of the canal was the high mortality from disease among the force at work. Situated on the beautiful hill of Ancon, overlooking the city of Panama, the French company constructed an excellent hospital which is used to-day by the Isthmian Canal Commission. The records of this hospital were well kept, and a good idea can be had of the mortality from yellow fever among the employees of the company. In nine years during the active period of work 1,041 patients died of yellow fever in the wards of Ancon hospital.

The construction of the canal was done by the contract system, and all patients were charged $1.00 per day for treatment in the hospital. As a result the majority of the sick were not treated in the hospital, as it was cheaper for the contractor to discharge them. Again, the hospital did not have a good reputation among the non-immunes, as a good many patients contracted yellow fever in the hospital. Everywhere in the grounds millions of mosquitoes were constantly breeding in the pools of water and the rank vegetation which was allowed to grow wild, but grimmest of all is the story of how mosquitoes were bred in the very wards of the hospital.

In the French days the patients in the wards were fearfully plagued by ants, which swarmed everywhere, causing much annoyance. To remedy this nuisance bowls of water were placed under every bed post, every chair leg, in fact, everything that touched the floor in the hospital. No heed was taken of the stegomyiæ larvæ contained in these bowls of water, no oiling was done. If they had set about devising a way of spreading yellow fever, they could not have hit upon anything more deadly than that.

The stegomyia mosquito is more of a house mosquito than the anopheles, and as the French depended almost solely for their water supply on rain water collected in barrels and cisterns, they were again breeding mosquitoes practically in their own households. The French averaged about 1,600 white employees on their rolls, and considering the number of deaths from yellow fever in Ancon hospital in nine years as being about one half the number of deaths from that disease, this would give a mortality of over 2,000 deaths from yellow fever among the French. This means that they lost five fourths of their force in five years.

These losses are put at a low figure, for from the survivors of small parties who worked on the canal in those days, a fearful loss of life is shown. The family of one of the chief engineers lost four from yellow fever, the family consisting of five; three out of five died in the family of the superintendent of the railroad. Out of a party of seventeen engineers, sixteen died of this disease; three doctors died from this in one week at Ancon hospital, two in one day. Of a force of twenty-four Sisters of Charity who came from France to supply the rapidly depleting nursing force of Ancon hospital, twenty died of yellow fever. It is estimated that one third of the Frenchmen who came to Panama died of this dread plague.

One of the construction camps now in use was built by the French. Of the first detail sent there to live, all contracted yellow fever with its consequent high mortality. All the furnishings of the house were destroyed, the house was thoroughly fumigated, new furnishings put in and the same thing happened again. After a third attempt the camp was abandoned. No one considered the swarming mosquito breeding amongst them. Yet in spite of these frightful losses by yellow fever, malaria and other tropical conditions, they excavated eighty million cubic yards out of the canal prism, completing about one quarter of the work. It is conceded by the American engineers that the French engineers did excellent work. The remarkable perseverance under the most adverse conditions have stamped their efforts to construct the canal as being really marvelous.

When the United States took possession, in 1904, there was very little yellow fever, as there was a non-immune population. On the other hand, malarial fever was very prevalent, the large majority of the native population harboring malarial parasites in their blood, in one village over eighty per cent of the population. It was recognized at the outset that the Panama Canal could not be constructed by the Americans unless the Isthmus was made reasonably healthy so that Americans could live there. So long as the health conditions remained bad it was impossible to keep a suitable laboring force on the Isthmus, not only on account of the present sanitary conditions, but

because the Isthmus had a world-wide reputation for unhealthfulness in times past.

To Col. W. C. Gorgas, U. S. A., was intrusted the organization of the sanitary department, as he was recognized as an expert on sanitation chiefly on his record in stamping out yellow fever in Havana in the remarkably short period of eight months. The three most important branches of the work in Panama were the eradicating of yellow fever, the controlling of malaria and the rigid quarantining of bubonic plague, yellow fever, cholera and smallpox. In July, 1904, a few months after the Americans took charge, the first case of yellow fever occurred in a white employee of the police department, who died. No other cases were reported for about a month, then eight cases developed in the city of Panama, practically all among Americans.

In January, 1905, the disease broke out in Colon, on the Atlantic side, and nineteen cases were recorded in the two cities during the month. For the next few months there was no alarming increase until the maximum was reached in June, when sixty-two cases developed. There was a gradual decline until Dec. 11, 1905, when the last case was reported in Colon. In all there were two hundred and forty-six cases and eighty-four deaths, the disease being confined to the cities of Panama and Colon. Since that time there have been two or three cases of yellow fever on the Isthmus, but these cases have been kept in quarantine, and no epidemic resulted. It took eighteen months to stamp out yellow fever on the Isthmus, and the work was pushed with the greatest vigor from the start. The city of Panama was fumigated as a whole three times, every house was included, besides fumigating each block every time a new case was reported. Over four hundred men were used in the fumigating squad, and two hundred thousand pounds of pyrethrum and four hundred thousand pounds of sulphur were used during that period.

The campaign against malaria was begun in July, 1904, and has continued uninterruptedly to the present time. The results obtained in fighting the disease have also been very satisfying, but necessarily slower on account of the conditions existing. The Americans suffered greatly from malaria in the early days; a vast majority of the employees who went to the Isthmus in the first few years contracted the disease. At one time in Colon hospital thirteen out of fifteen doctors on duty in the hospital had malaria, most of these cases of the ambulatory type. The anopheles mosquito breeds in fresh water where grass and algæ grow, and is principally a breeder in the country districts. It does not fly more than two hundred yards, although it may be carried by the wind much farther. All the breeding places in the immediate vicinity of the camps and villages were destroyed either by filling in or by surface or subsoil drainage, together with a certain amount of oiling. At the same time all houses were thoroughly screened and the beds of the employees were fitted up with mosquito bars. Prophylactic doses of quinine, 5 to 10 gr. daily, were strongly advised to be taken by the men at work. Results from the energetic work against malarial fever soon began to show, and the mortality decreased year by year.

In 1905 the malarial rate per thousand was 514; in 1906 the rate was higher, 821 per thousand, a total of 21,938 employees being treated for malaria. The rate diminished over 50% the next year, and in 1908 but 282 per thousand. Since then the rate has been slightly less, but showing a definite diminution in malaria among the working force. At the present time the vast majority of Americans who go to the Isthmus to work escape malarial fever.

Only three cases of bubonic plague have developed on the Isthmus since American occupation, — one case in 1905, another in 1906, and the last case in 1909, all coming in on boats from South America. Following each case thorough fumigation of the quarters occupied by these patients was performed, and a crusade against rats, the common carriers of plague, was carried out. Rat traps were issued free to all persons who wished them, and a small bounty was placed on each rat delivered to the health department, which agreement is still in effect. In spite of the fact that ports on both the Atlantic and Pacific sides of the Isthmus, north and south, have been infected with bubonic plague, in some places in epidemics, the Isthmus has remained free from an epidemic up to the present time, due to the excellent quarantine which is kept up against the infected ports. This is the one disease which would tend to delay the work on the canal if it should get a foothold in Panama. It is much more feared by the native population, as they are not immune to this disease as they are to yellow fever.

Smallpox has never been a factor since American occupation, as all employees are vaccinated before landing, and only a few cases have been recorded in the early days of the American occupation. Amebic dysentery has been a fairly common disease among the Americans, although proportionately much less than among the Americans in the Philippines. Since the installation of a good water system in all the towns along the canal, police patrols guarding the reservoir, the prevalence of amebic dysentery has diminished to a marked degree. A condition more feared by the Americans on the Isthmus is liver abscess, one of the complications of amebic dysentery. This condition caused about twenty-five per cent of all the deaths among the American employees during the first four months of last year. The occurrence of mild epidemics of typhoid fever from time to time among the negroes, especially about Gatun, has never caused any alarm, as the number of cases and deaths has been small. The disease takes a much milder form there than up here in the temperate zone. Uncinariasis or hookworm disease is still very common among the native population, but the treatment of the condition among them has lessened its prevalence considerably. It is very rare that an American contracts this disease, and as soon as it is recognized is

immediately treated and cured. During the two years 1906 and 1907, a very severe epidemic of pneumonia prevailed among the West Indian negroes working on the canal. About thirteen hundred cases occurred during that time, and the mortality averaged about forty per cent of these cases. The native Panamanian averaged a much higher mortality than the West Indian negroes, being a race with several mixtures, the Indian and negro bloods predominating.

A very complete and interesting line of research was undertaken by the sanitary department to find out any causative factors in the spread of this disease among the negro laborers. The investigation included such physical conditions as might influence the occurrence of pneumonia. Several camps along the line of the canal were examined, going over the houses carefully, examining the modes of living, noting the location of the place, whether wet or dry, the amount of ventilation in each house, whether they were overcrowded, and noting from the books of each district physician the amount of malaria and the number of cases of pneumonia sent to the hospital. The object of this investigation was to examine carefully the places where the pneumonia was very prevalent, and the places where it was least prevalent, to see if there were any conditions in the locality, houses or mode of living to explain the differences. It was necessary if possible to pick out camps which were as nearly as possible under the same physical conditions, such as dampness, elevation, crowding, lack of ventilation, and also as regards the presence of malaria, to see if any of these factors seemed to come in as causative or preventive of the epidemic of pneumonia.

The result of this investigation gave some interesting negative findings. The epidemic of pneumonia was not affected by the season of the year, as in 1906 it was worse in the wet season, while in 1907, in the dry season, it was much worse than in the wet season of 1906. It made no difference in the rate whether the camp was located in a high altitude or in the valleys, and lack of cleanliness, overcrowding, exposure to draughts or living in houses without any ventilation seemed in no way to affect its prevalence. The malaria rate also had no effect on the frequency of the pneumonia cases. One factor alone seemed to bear any relation to the disease. Pneumonia was inversely prevalent with the length of stay on the Isthmus. By dividing the commission employees into those who had been on the Isthmus over three months and those who had been on the Isthmus less than that time, it was found that the proportion of cases among the second class was considerably greater than in the first, about five to two. The recent arrivals showed considerably more susceptibility, probably due to two factors. First, that the newly arrived laborer did not know how to take care of himself, and, secondly, he was almost certain to be attacked by the grippe, which was very prevalent on the Isthmus at the time, while the older men, having passed through the influenza period, were less liable.

I might say in relation to this disease that, associated with a large number of pneumonia cases, and recognized at autopsy, were rhinitis and sinusitis. The sinuses were involved in about sixty-one per cent of the cases coming to autopsy, the pneumococcus being found in most of these cases in the purulent exudate.

There is one disease on the Isthmus which is causing more deaths than any other condition at present, namely, tuberculosis. The negroes and the native Panamanians, on account of their racial susceptibility, their methods of living in overcrowded houses, the disease has continued unchecked and is at present a big factor in the mortality statistics. This disease runs an especially acute course, averaging about six months from beginning of symptoms until the death of the patient.

The sanitary department have two large terminal hospitals, one at Ancon, the other at Colon, with small dispensaries and hospitals along the line of the canal which feed the two main hospitals. The patients are sent in from the line on the hospital cars which are a part of every regular passenger train that crosses the Isthmus. In any emergencies special engines and trains are always available for the transportation of the sick or injured to the hospitals. There is a force of about one hundred physicians, about fifty of whom are located in Ancon and Colon hospitals, and the rest along the line of the canal in the smaller dispensaries. Besides the force of physicians and nurses, there are sanitary inspectors connected with stations along the line of the canal, whose duties are to superintend the cutting of the brush, draining of swamps, oiling of mosquito-breeding areas and fumigating infected houses.

The largest hospital on the Isthmus is Ancon hospital, established by the old French company in 1883, and added to by the Americans. It is situated just outside the city of Panama, on the northern slope of Ancon hill overlooking the Pacific Ocean. It covers an area of about eighty acres and comprises ninety-six buildings, most of which are of frame construction, and thoroughly screened. The hospital including the insane asylum has a normal capacity of 1,170 and a maximum capacity of 1,350 beds. All employees are treated free, and the members of employees' families are charged one dollar a day. The hospital in every way compares favorably with any large city hospital in the United States, having forty-nine wards, twenty-three of which are for medical cases, eight for surgical, three eye and ear, one tubercular, one isolation and eleven insane. There is an excellent large operating room, equipped to handle any number of cases, also an x-ray outfit, and a board of health laboratory. The medical staff consists of twenty-five physicians and seventy-five nurses.

Colon hospital, which adjoins the city of Colon, faces the Caribbean Sea and comprises forty frame buildings. The greater number of these wards are built on brick and concrete pillars on a coral reef which is covered by the sea except

at low tide. The capacity of the hospital is about one half that of Ancon hospital, namely, about six hundred beds. The medical and surgical organization is similar to that at Ancon hospital and the equipment is practically the same. The staff consisted of sixteen physicians and forty nurses.

Taboga Sanatorium, situated on the island of Taboga, in the Pacific Ocean, is for white employees who are convalescing from sickness contracted on the Isthmus. Here on the island convalescents may stay from one to two weeks until they are ready to resume work.

The mortality rate shows a definite reduction from year to year. In 1904, when the population was small, we had a death-rate per thousand of 52; the following year a somewhat higher rate, about 65 per thousand, and in 1908 it had dropped to 24 per thousand; last year, 22 per thousand, corresponding favorably with the mortality in any of our large American cities. A constant and absolute medical supervision has brought about these remarkable results in the health conditions on the Isthmus, and eternal vigilance is necessary to preserve such conditions.

While working in the American medical wards at Colon hospital in 1908, I was impressed by the large number of neurasthemic cases among the American employees. The continued high humidity, the exposure to the hot tropical sun while working in the open, has a good deal to do with the prevalence of neurasthenia among the Americans at work on the canal. Most of these patients required at least a week of absolute rest and quiet in the hospital, and another week to convalesce at the government sanatorium at Taboga Island.

American women do not seem to tolerate the climate of the Isthmus well. One of the most common symptoms noted is menorrhagia, and neurasthenia is common after a prolonged stay of two years or over. These facts justify in my opinion, that, despite the marked improvements in sanitary conditions which are bound to follow the example of the United States on the Isthmus of Panama, the climatic conditions alone are enervating enough to prevent the white race from ever getting a permanent foothold on the tropical regions, and dispute the claims made by some of our sanitarians that the tropics will soon be a paradise for the white race.

## SOME OF THE MORE IMPORTANT DISEASES OF THE UPPER ABDOMEN THAT MAY REQUIRE SURGICAL INTERVENTION.*

BY JOHN W. KEEFE, M.D., PROVIDENCE, R. I.

EVERY practitioner of medicine meets with numerous cases that present symptoms referable to derangements of digestion and for want of a more accurate diagnosis are called dyspepsia, attacks of indigestion, bilious attacks, *et cetera*.

I shall call to your attention the symptoms and signs of some of the diseases most frequently met with in the upper abdomen in order that we may be better able to locate the lesion present and learn something of its characteristics, thus enabling us to formulate a logical line of treatment.

One may be able to make a correct diagnosis of any of these diseases if an accurate history is obtainable and the typical symptoms and signs are present. We may have more than one diseased condition present, as frequently infection of the bile tract secondarily involves the pancreas. Then there are cases where many of the characteristic symptoms are wanting, rendering it impossible to make a correct diagnosis.

Diseases of the upper abdomen should be looked at both from a medical and surgical standpoint. It is very natural that the internist should have a different viewpoint from the surgeon. A surgeon has the advantage of seeing the pathological changes that have taken place in the living subject, besides having an opportunity of knowing the history of the case and making a physical examination. The internist could add to his knowledge of disease by attending operations upon his patients and seeing the marked pathological changes that have occurred with perhaps but few well-defined symptoms present.

A number of diseases considered but a few decades ago as amenable only to medical treatment we now know can be relieved or cured by surgical intervention. We know that an ulcerated area in the stomach or duodenum may undergo a malignant change. This should be an argument for us not to think too lightly of ulcer, but to attempt early and radical operation where medical treatment has failed to give relief. If we have definite evidence of chronic ulceration of the stomach or ulcer of the duodenum, infection of the biliary tract, or pancreatitis, methods for surgical relief should at least be carefully considered. Personally, I should prefer an abdominal section if medical treatment had been of no avail, and give a competent surgeon an opportunity to render surgical assistance should relief be possible.

Hyperacidity and pyloric spasm and motor insufficiency are regular accompaniments of ulcer of the stomach or gastric ulcer. Twenty-five per cent of both acute and chronic gastric ulcers treated medically die from perforation, hemorrhage or cancer. Gastric ulcer is also prone to recur. Chronic ulcer is frequently followed by carcinoma. Gastric ulcer has been shown by autopsy findings to have run its course and healed without producing any recognizable symptoms during life. The cardinal symptoms are vomiting of blood or its passage with the stools.

*Disturbances of digestion.* — The symptoms are vomiting, epigastric pain and tenderness, hyperacidity, hematemesis or melena, namely, the passage of dark tarry blood with the stools. In chronic ulcer of the stomach the patient suffers pain upon the entrance of food into the stomach. Motor insufficiency of the stomach occurs in the later stages of the disease. Ulcer of the pylorus may be accompanied by obstruction of the same due to the cicatrical contraction which takes place about a chronic ulcer, and should this be

*Read before the Providence Medical Society, Providence, R. I., Nov. 7, 1910.

marked, symptoms of motor insufficiency may follow.

In gastric ulcer there is usually a greater amount of HCl than that normally present in the stomach. The many exceptions, however, to this rule renders it of value only when considered in connection with other symptoms and signs.

The physical signs are localized tenderness in acute ulcer. In chronic ulcer there is tenderness on deep pressure. There is a sense of resistance felt should there be infiltration about the ulcer. The inflammatory infiltration about the pyloric end of the stomach may be palpable in thin subjects, but a mass that can be felt is usually more likely to be carcinomatous in character. When the peritoneal coat of the stomach is involved, we may have adhesions to the abdominal wall, and subsequently an intramural abscess.

Adhesions to the duodenum, colon and pancreas may result from gastric ulcer and there may be a sense of resistance on abdominal palpation. When a gastric ulcer perforates into the general peritoneal cavity the patient complains of a sudden severe pain over the region where the perforation took place. Shock follows; the pulse is rapid and feeble; the countenance is pale, pinched and anxious. The breathing is rapid and shallow. The abdominal muscles are rigid and hard to the touch. Vomiting is an early symptom. The pain and tenderness at first localized over the site of the perforation later becomes general. The abdomen which was retracted becomes distended. In the course of five or six hours we may have a diffuse peritonitis. Perforation may be the first symptom of a gastric ulcer. Immediate operation should follow early recognition of a gastric perforation. The location of the greatest point of pain and of tenderness on pressure soon after the perforation takes place is the most important sign in the differential diagnosis.

The greatest point of tenderness is usually found over the right or left rectus muscle above the umbilicus. Should diffuse peritonitis be present, the previous history of the patient may be of aid in making a diagnosis, but usually the patient is so ill that a good history is unattainable. The probable diagnosis can then be made of a peritonitis following a perforation of some hollow viscus, namely, the stomach, duodenum, gall bladder or appendix.

Patients usually arrive at our hospitals without a written description of their illness either by their physician or friends. The patient, on account of his illness or not understanding our language, may be unable to give a description of his sickness and the hospital physician is at a disadvantage in making a diagnosis.

This lack of a correct history may result in the death of the patient. You can readily see that if a diagnosis of appendicitis or salpingitis is made when the diseased condition is a gastric perforation or acute hemorrhagic pancreatitis, an unnecessary operation which discloses a normal appendix or fallopian tubes may be sufficient to hasten the death of the unfortunate patient, while a history of the case by an intelligent observer, especially the conditions present in the early stages of the disease, may be the means of saving life. The physician who sends a case to the hospital should feel that it is his duty to his patient to write a concise history of his illness and send it with the patient to the hospital. The physician can usually, through the patient, family or friends, or perhaps with the aid of an interpreter, obtain a satisfactory account of the illness, and this should be properly attended to if we have the love we should have for our fellowman.

The anatomical situation of the duodenum in relation to the adjacent organs renders a diagnosis of ulcer of the duodenum difficult. These ulcers occur most frequently in men from thirty to sixty years of age. There is usually a history of dyspepsia covering a long period. One of the earliest symptoms is vomiting, which occurs several hours after the ingestion of food, usually from two to four hours. The vomitus is acid, chyme, and rarely contains blood or bile. Vomiting affords immediate relief. The tongue is clean and the appetite good. The pain is located to the right of the median line just below the gall bladder and does not radiate around to the back; it comes on suddenly and is colicky in character. The most reliable of all symptoms is the appearance of blood in the stools. The blood found may be fresh or dark and tarry in appearance, showing evidence of digestive changes. Jaundice may be present, due to inflammatory edema, which obstructs or distorts the common duct.

Perforation is the most frequent and dangerous complication of duodenal ulcer. The pain is usually greatest in the right hypochondrium, but it may pass down to the right iliac fossa. Shock, as a rule, is not present, and if it occurs it is not usually severe. The peritonitis which follows perforation extends from above downward.

We should cease telling our patients that they are suffering from the presence of gallstones, as at operation we may find no gallstones present. Infection of the bile tract is a better and more correct term to use. The gallstones when present are always preceded by infection and subsequent inflammation of the bile tract which causes retardation of the flow of the bile and precipitation of the bile salts. Both typhoid and colon bacilli have been found in gallstones, and gallstones have been caused to form in the gall bladders of rabbits by the injection into the gall bladder of a rabbit, typhoid and colon bacilli, streptococci and staphylococci.

While we know that after the formation of gallstones these may cause ulceration and obstruction of the bile passage, we must remember that we can have the same symptoms produced by swelling of the mucous membrane of the bile ducts, due to infection and inflammation without the presence of stones.

What is commonly called biliary colic is frequently due to distention of the gall bladder caused by obstruction of the cystic duct due to swelling of its mucous membrane or plugging

with thick and viscid bile. A number of times while irrigating a sinus leading to the gall bladder I have caused severe pain by distending the gall bladder with the normal salt solution and the patients have said that the pain was exactly similar to that which they had experienced before operation. I have seen many cases where the patient had what is known as gallstone colic and at operation showed only an infection of the bile tract with no evidence of gallstones.

Let us be contented, then, with a diagnosis of infection of the bile tract and say nothing as to the presence of gallstones. It is as necessary to relieve this condition by drainage of the gall bladder and so prevent the formation of gallstones as it is to remove gallstones and drain the bile passages.

Infection of the biliary passages usually occurs in obese and phlegmatic individuals. The pain, paroxysmal in character, more often occurs at night and has no relation to the ingestion of food. It is greatest over the region of the gall bladder in the right hypochondrium and is referred to the back and shoulder under the angle of the right scapula. There is definite local tenderness over the gall-bladder region. The vomiting is copious and recurring. A chill frequently ushers in the paroxysm and is followed by an elevation of temperature. The chills and fever may recur and give rise to an erroneous diagnosis of malaria. The pulse is often abnormally slow. Jaundice may or may not be present, depending upon the presence or absence of obstruction in the hepatic or common ducts. Marked disease of the gall bladder with or without stones may exist without the presence of jaundice. There is muscular rigidity of the right rectus muscle, and at times a tumor may be detected in the region of the gall bladder. We may have a history of previous attacks and a stone may have been found in the stools. Although a stone may be found in the feces, others may yet remain in the gall bladder.

Diseases of the pancreas have a close relation to infection of the bile tract and as a rule are preceded by such infection. Drainage of the gall bladder will, in consequence, frequently relieve disease of the pancreas.

*Etiology of pancreatitis.* — The relative positions of the pancreatic and common bile ducts, and the frequency with which the bile channels become infected, and the subsequent tendency to the formation of biliary calculi, renders the pancreas vulnerable, most commonly at the ampulla of Vater. The most common cause of pancreatitis is some infection of the biliary tract. Infective material may be carried to the pancreas through its ducts. A gallstone may become lodged in the ampulla of Vater, occluding the outlet for the bile, through the greater papilla, and yet the stone may be so small that it does not completely fill the ampulla, thus allowing the bile to enter directly the pancreatic duct. A stone arrested in the common bile duct, at a point where this duct lies parallel with the pancreatic duct in the head of the pancreas, may so press upon the latter duct as to cause occlusion of the same, thus preventing the outflow of the pancreatic secretion.

Enlargement of the head of the pancreas from any cause may produce occlusion of the common bile duct and produce secondary changes in the bile ducts and liver. Catarral jaundice may be produced in this manner. Infection of the pancreas may occur by way of the blood vessels or lymphatics. Near the head of the pancreas we find that the efferent lymphatics from the gall bladder meet the efferent lymphatics from the pancreas. Intestinal bacteria may enter the ampulla of Vater following the dilation of its duodenal opening by the passage of a stone. Pancreatic calculi may occlude the pancreatic duct and give rise to symptoms. The characteristic pathology found in acute pancreatitis is fat necrosis.

Symptoms of pancreatitis are acute, occasional attacks of indigestion, previous history of infection of the bile passages, sudden excruciating pain in the epigastric region, radiating to the left and through to the back. The pain is more severe than that due to gastric perforation or gallstones. The large doses of morphia necessary to give relief may lead us to think of pancreatitis. Nausea followed by vomiting at frequent intervals occurs, but the material ejected is seldom fecal in character. The sudden seizure is followed by collapse or varying degrees of shock. Frequently there is cyanosis or lividity and the facial expression is extremely anxious. Dyspnea is a prominent symptom, and hiccough may be very distressing. The temperature at the onset is subnormal and may be but slightly elevated even in the later stages. Cases, however, have been reported where the temperature has been high, but this occurs usually after secondary changes have taken place. The pulse-rate is increased and the pulse is feeble; at times it may be scarcely perceptible. There is rigidity in the epigastric region, most marked over the left rectus muscle, and there is tenderness on pressure, most pronounced midway between the end of the ninth rib and the umbilicus. Soon the abdomen becomes distended and is tympanitic on percussion. There is a board-like rigidity over all the abdominal muscles. Deep pressure in the costo-iliac space causes pain. Usually the bowels are constipated, so much so that cases have been mistaken for intestinal obstruction. A mass may be palpated in the epigastric region in some instances. Jaundice may precede or occur during the attack.

There is a leucocytosis present and especially an increase in the polymorphonuclears. Sugar may occasionally be found in the urine, during the early stages of the disease, but usually it is absent. Fat may be found in the feces, which are soft and look like butter, or they may be oily and very offensive. Should the pancreas undergo complete degeneration, the muscle fibers found in the stools contain nuclei. The Cammidge reaction is considered by a number of competent observers to be of no value. Should there be found beef-broth-like serum in the abdominal

cavity, and the omentum and mesentery studded with white or yellowish plaques of fat necrosis, we should at once look to the pancreas as the cause of this condition.

*Carcinoma of the stomach.* — In gastric cancer the vomiting is that of pyloric obstruction. The blood found in the vomitus is of a characteristic coffee-ground appearance. There is loss of appetite, with emaciation and cachexia following. Examination of the stomach contents showing the absence of HCl and the presence of lactic acid is practically conclusive evidence of cancer.

We may be able to feel a growth, or there may be general lymphatic involvement with metastatic growths. With the exception of cancer, and occasionally these cases may be relieved, the other diseased conditions found in the upper abdomen may be amenable to surgical measures. Medical treatment alone may be sufficient to relieve or cure in certain cases, but where medicine has been given a fair trial without giving relief, surgery should be resorted to. Some of these patients will require immediate operation as life-saving measures, while others are not so urgent and yet surgery should not be too long delayed if we wish to effect a cure. The frequency with cancer may follow comparatively innocent derangements is a strong argument in favor of early surgery.

To sum up:

*Ulcer of the stomach.* — Hyperacidity, hematemesis, pain directly after eating.

*Ulcer of the duodenum.* — Blood in the stools. The pain which comes on three or four hours after eating does not radiate to the back. It is localized just below the gall bladder.

*Gall-bladder infection.* — Chills, fever, pain over gall bladder, intermittent in character, nausea and vomiting.

*Pancreas.* — Sudden onset, marked prostration, dyspnea, lividity, cyanosis, intense pain. Upon opening the abdomen, beef-broth-like serum. Areas of fat necrosis.

*Cancer of the stomach.* — Vomitus resembles coffee grounds.

Absence of HCl. Growth may be palpated. Cachexia.

Send a short history of your patient when sending him to a hospital.

Beware of those cases called chronic nervous dyspepsia, et cetera.

Look for some definite pathology of organic disease.

Remember that infection of the bile tract always precedes the formation of gallstones.

## MONGOLIAN IDIOCY.*

BY WILLIAM N. BULLARD, M.D., BOSTON.

THE term "Mongolian idiocy" was first suggested by Langdon Down, in 1866, in an article entitled, "Observations on an Ethnic Classification of Idiots," in the London Hospital Reports (Vol. iii, p. 259), as applicable to a distinct class among the idiots or feeble-minded on account of the supposed resemblance of these patients in facial type to the Mongols or Kalmucks.

It was found on more extended examination of these persons that they did form a distinct class, not in appearance only, but in other characteristics, and they have been for many years distinguished from those afflicted with other forms of mental weakness or idiocy.

At the present time it is possible to state the typical physical characters and distinguishing peculiarities of these defectives more or less clearly. These are as follows:

1. In the first place, Mongolian idiots almost universally show signs of general arrested development. They are small and symmetrically developed but appear, especially during the period of growth, like children two or more years younger than they actually are. Thus a Mongolian idiot of fifteen is apt to present the appearance of a child of twelve or thirteen.

2. Another symptom characteristic of Mongolian idiocy is brachycephaly. The cranium is in these patients not only small and often so disproportionately small as to be technically microcephalic, but it is brachycephalic; that is, the transverse diameter is excessively large in proportion to the shortened anteroposterior diameter. It immediately suggests itself that this condition may have some relation to the shape or size of certain bones at the base of the cranium and may influence or cause some of the other peculiarities, mental or physical, belonging to this type, but no evidence of this has yet been shown. In fact, it seems to be distinctly proved that early synostosis of the tribasilar is *not* the cause of this condition.

3. The occiput is apt to be steep or flat.

4. The face of the Mongolian idiot is usually wanting in intelligence, dull or stupid in expression.

5. One of the most obvious and characteristic signs of this condition is the slanting direction of the eyes, that is, of the eyelids and the space between them. This is almost a pathognomonic sign, yet it is said to occur exceptionally in other forms of idiocy and even occasionally in the otherwise normal Caucasian. This condition is frequently accompanied by an epicanthal fold, and in one of our cases the line of the upper eyelid was so extended as to form a distinct fold above the external canthus.

Strabismus is not rare, but is not distinctive. Nystagmus is said to be often present in the first six months of extra-uterine life. The face is often broadened and flattened; the nose broad, its bridge sunken and the nostrils facing upwards, thus resembling the face of the cretin or cretinoid idiot. In many cases, however, this facial form is not present.

The skin of the face is delicate, thin, easily roughened. The mucous membranes are extremely sensitive and liable to irritations and inflammations, particularly blepharitis and nasal catarrh. It is said that when certain of these

* Read in abstract at the meeting of the American Neurological Association, 1909.
Roentgen plates taken by Dr. A. W. George.

FIG. I. Shows three boys of the ages of eighteen, thirteen and nine years respectively. The middle one, thirteen years old, is a negro. Mongolian idiots.

FIG. II. Shows also three boys with typical faces. Note the peculiar thinness of the skin of the face and the half-closed eyelids, suggesting blepharitis, in the middle boy.

FIG. III. Girl Typical facial expression, more nearly resembling the cretin type.

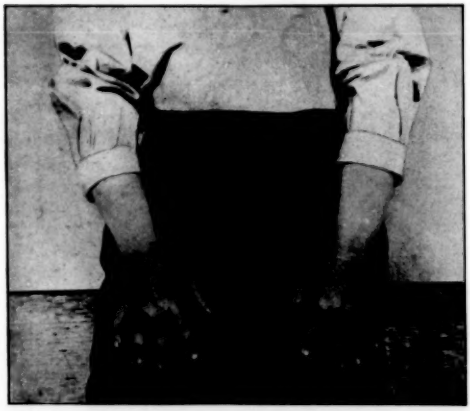

FIG. IV. Typical hands, short, broad and stumpy.

PLATE I. Hand of female Mongolian idiot ten years old. The bones of the carpus are all present, including the pisiforme. The hand is smaller than normal and the bones more slender.

PLATE II. Hand of normal child ten years old.

PLATE III. Hand of male Mongolian idiot seventeen years old

PLATE IV. Hand of normal person seventeen years old.

Plate V. Foot of patient whose hand is represented in Plate I, girl ten years old. The foot is correspondingly smaller than the normal. There is nothing unusual about the structure.

PLATE VII. Normal foot child ten years old.

PLATE VIII. Cranium of ten-year-old Mongolian idiot. Compare Plates I and V, same patient. This cranium is rather under the average size. The sella turcica seems a little larger than the average. The teeth are irregular in size, shape and position.

PLATE IX. Cranium of patient whose hand and foot are shown in Plates III and IV, seventeen years old. Frontal suture wider than normal. Unerupted canine.

patients cry their eyelids swell like bladders and may become everted.

These patients need special protection from cold.

Almost pathognomonic also is the appearance of the tongue, which shows deep, sharp-edged, more or less transverse fissures in its anterior and middle portions. These do not appear at birth; the earliest date of appearance noted seems to have been at twenty-two months. Hypertrophy of the fungiform papillæ is reported. Muir states that palatal deformities occur in 65%.

The teeth are apt to be irregular in size, shape and position.

The thyroid gland is normal.

*Internal organs.* — Congenital heart disease is frequent. Non-closure of the interventricular septum and persistance of the ductus arteriosus are found. No other special anomaly of the internal organs has been noted.

*Laxity of the joints* is most striking. It is apt to be specially marked in the hips. These patients have the habit of sitting tailor-fashion. One of those examined by us used to shut himself up like a jackknife, each foot on the opposite shoulder, and thus sleep at night.

In appearance, the long portions of the limbs do not differ from those of the normal person of the same age except in being often symmetrically smaller. The hands are short, flat and stumpy. There is said to be at times a disproportionate shortness of the thumb and of the fifth finger. Much has been written about the peculiar inward curve of the fifth finger, but this is not always present and, moreover, has been found to occur in other varieties of defectives and in normal persons, and is not characteristic.

The feet are usually normal in appearance except as regards size. They may appear short and stumpy like the hands. The toes may have unusual or irregular proportions in relation to each other. The feet and legs are often cold and blue and show evidence of imperfect circulation.

The deep reflexes were in our cases all normal (25 cases). Fennell reports that out of 20 cases they were brisk in 9, normal in 6 and absent in 5.

Umbilical hernia is not rare.

Bourneville (1903) found in his cases delay in the ossification of the cartilages of the long bones.

*Pathological anatomy.* — Autopsies on these cases have contributed little to our knowledge of their causation, or even of the existing pathological conditions. Wilmarth found an unusual smallness of the pons and medulla, but nothing else peculiar. Shuttleworth says "The brain is characterized by great simplicity of development and by paucity of multipolar cells. The convolutions are large and coarse, and there are few secondary convolutions."

In view of the well-defined symptoms and signs of Mongolian idiocy by which a well-marked case is so easily differentiated, it has seemed to us of interest in our general study of the pathological conditions of bone and cartilage growth and formation as shown in achondroplasia and other allied states to make a careful x-ray examination of the conditions in patients of this class.

My results are based on the x-ray examination of 25 Mongolian idiots from the Massachusetts School for the Feeble-Minded at Waverley, and my special thanks are due to the superintendent, Dr. Fernald, for his kindness in allowing me to make this study.

### DESCRIPTION OF PLATES.

All plates show the part represented *natural size*, excepting Plates VIII and IX, which are reduced.

The Roentgen plates of these cases show chiefly differences in size and stage of development between these patients and normal persons of the same age. There are no characteristic changes of structure such as are found in achondroplasia or osteomalacia. The development, however, has been distinctly retarded and it has seemed that this occurred to a greater degree, the younger the individual. This retardation has shown best in the carpus and the long bones of the forearm. In some cases there has apparently been no development in size or ossification for three or four years. Between the ages of ten and twenty, ossification has in the majority of cases been delayed. In two cases, however, it was more rapid than in the average normal person.

No evidence is shown of change in the structure of the bones, though there is some irregularity at times in the shape of the first metacarpal and of the os calcis. The bones of the head and face appear normal, but the closure of the anterior fontanelle is sometimes delayed. The development of the teeth in all the cases examined has been abnormal either as regards time of eruption or number or position.

The size of the long bones in the majority of cases is *smaller* than normal. Their structure is not peculiar.

## Reports of Societies.

### AMERICAN PUBLIC HEALTH ASSOCIATION.

THIRTY-EIGHTH ANNUAL MEETING, HELD AT MILWAUKEE, WIS., SEPTEMBER 6, 7, 8 AND 9, 1910.

THE Association convened in the Auditorium, with the President, DR. CHARLES O. PROBST, Columbus, Ohio, in the chair.

#### REPORT OF THE JOINT COMMITTEE ON MAILING INFECTIOUS MATERIAL.

DR. JOHN F. ANDERSON, of Washington, D. C., said that the proposed modifications of the regulations of the mailing of infectious material had finally been promulgated by the Post-Office Department under date of April 22, 1910. The committee believed that its efforts had resulted in the promulgation of regulations which were a decided improvement over those formerly enforced. The regulations have been considerably simplified. The committee was successful in having the privileges of the mails for the transmission of infectious

material extended to include federal, state, municipal and other laboratories upon the issuance of a formal permit by the Postmaster-General.

The report of the committee was accepted, and the committee discharged.

### STUDIES ON SELF-PURIFICATION OF STREAMS.

DR. G. F. RUEDIGER, Grand Forks, No. Dak., detailed a series of experiments on this subject, and then presented the following conclusions: Colon bacilli and typhoid bacilli disappeared much more rapidly from polluted river water during the summer months than during the winter months when the river was covered with ice and snow. The destruction of these organisms in the river water during the summer months was in a large measure due to the growth of microscopic plants and other organisms which apparently gave off dialyzable substances which were harmful to the bacillus coli and bacillus typhosus. That such substances were given off by the saprophytic bacteria was clearly shown by Frost several years ago, and his experiments simply confirmed Frost's by attacking the problem in a slightly different way. These effects were lost in the winter as no growth took place after 0° C. The direct rays of the sun also were an important factor and their effects were entirely lost when the river was covered with a thick layer of ice and snow.

The practical value of this investigation was very evident. It explained why some of the northern cities where sewage-polluted river water was used in the water-works system were more frequently troubled with outbreaks of typhoid fever during the winter months. This was illustrated at Minneapolis last winter, and he believed was true at Lawrence, Mass., before the installation of the filter.

When bacteriological analyses of sewage-polluted river water were to be made at the site of a proposed water-works intake pipe, it was important that samples should be collected and analyzed both in the winter and in the summer. Analyses of samples collected during the summer did not give reliable information in regard to the condition of that water when the river was covered with ice and snow. The analyses showed that the pathogenic bacteria from the sewage traveled several times as far in the water under the ice, before they were destroyed, as they would in an open river during warm weather.

#### DISCUSSION.

DR. H. W. HILL, of Minneapolis, Minn., said the experiments which they undertook confirmed in every way the observations and conclusions of the essayist regarding winter river typhoid and summer typhoid. They had found that typhoid bacilli might kill out in going down the river in summer under conditions where they would exist during the winter.

DR. PETER H. BRYCE, Ottawa, Canada, said he noticed in connection with the paper the author seemingly did not take into account the question of sedimentation during the two days in the river. They all remembered Pettenkofer's tests long ago at Munich showed about 90% of all bacteria in water by dilution and by sedimentation had disappeared within a distance of ten miles.

DR. E. C. LEVY, of Richmond, Va., said at the Winnipeg meeting of this Association Dr. Freeman and he presented a joint paper on typhoid fever in the South, with special reference to the disease in Richmond. In that paper they brought out the point which had been explained to-day, but made no attempt to explain why it was water-borne typhoid was especially a disease of winter months, but they proved to their satisfaction that such was the case. Their opinion was arrived at purely and simply from an epidemiological standpoint. They had no laboratory facts to corroborate this. During the years since that time their views had been confirmed in every way to such an extent that in Richmond, after they had passed the winter months, they did not worry about water typhoid.

DR. RUEDIGER (closing) stated he should like to say a word with reference to sedimentation, which was referred to by Dr. Bryce. He did not think the factor of sedimentation would alter the experiments in any way; so far as he could see, there would be as much sedimentation in winter as in summer. This factor need not be considered in this particular study. Another study might be based on the factor of sedimentation, which he believed would be the same in summer as well as in winter.

### THE SANITARY REGISTRATION OF HOUSES IN MEXICO.

DR. JESUS E. MONJARAS, of Mexico City, said the Board of Health in Mexico had made great progress in the sanitary records in that city. The plan of the city showed the houses in which persons had died of tuberculosis. Each house was shown on the plan by a number which corresponded to the number of cases observed in that house, and each one had its separate file containing all the details of cases as well as the work which had been ordered to improve the sanitary conditions of the houses. With this plan they were able to show the number of deaths caused by tuberculosis or any of its allied affections from the year 1891, with the ages and sex of those who died, and the wards in the city of Mexico in which those deaths were recorded. The sanitary registry of the houses, therefore, constituted a necessary institution in all cities, by the aid of which the sanitary and municipal authorities, as well as the general public, could obtain easy and certain knowledge of the houses which constituted foci of infection.

#### DISCUSSION.

DR. FREDERIC TORRALBAS, Havana, Cuba, stated the work the essayist had described had been carried on in Havana for some years. It was the duty of the sanitary inspector to cover the complete history of houses. An inspection was made of from eighteen hundred to two thousand houses a day, so that cases of tuberculosis were easily traced.

### SANITATION OF BAKERIES AND RESTAURANT KITCHENS.

MR. CHARLES B. BALL, of Chicago, stated in their experience with bakeries and restaurant kitchens they were led to the conclusion that new installations of restaurant kitchens were required. Ample space must be provided in which the employees might perform the various operations. The contingency of expansion at a future date should be considered, as the tendency to enlarge the dining room, without providing additional kitchen facilities, was found in a great many cases. The arrangement of the various appliances in their relation to each other should insure the isolation of dishwashing and garbage storage from the handling of food. Adequate provision must be made for the removal of cooking odors, not alone from the ranges, but also from vegetable boilers, so as to avoid nuisance in other parts of the building and in the neighborhood. The Underwriters Association now required that ventilation ducts from large ranges be built of heavy iron plate and carried through the top of the building without any other connections, so that the grease and soot may be burned out of them as from a chimney flue, without incurring fire danger to other rooms. Ample toilet facilities and wash-rooms, separate for each sex and

apart from those provided for the public, must be furnished. The wash-basins should be located outside of the toilet rooms in order that it might be apparent to those in charge that the hands are cleansed after leaving the toilets. Proper locker rooms with exceptional means of ventilation must be provided in order to avoid the nuisance of the storage of either street or working clothes in tightly closed cupboards. Well-ventilated refrigerators were required in numbers sufficient to afford separation for the different classes of food, and especially for milk and butter. The best examples of the application of these rules of design to new bakeshops and kitchens were to be found in upper stories, preferably the top story, of certain high buildings. Such installations of superior type were at present by no means rare.

### PRACTICAL METHODS OF SUPERVISING THE MILK SUPPLY OF CITIES.

Mr. J. Bosley Thomas, of Baltimore, Md., discussed permits for the sale of milk and cream; methods of keeping records; collecting samples and recording results; methods of transporting and delivering milk; communicable diseases; diseases in houses where milk was delivered in bottles; bovine tuberculosis; supervision of dairy farms; butter-fats standards, and said that while there were many admirable methods used by various authorities in the administrative control of the milk supply, there was little or no standardization of these methods. It, therefore, seemed advisable that some representative society or body should appoint a committee to establish or recommend standard practical methods that would be capable of universal use.

### SAVING CHILDREN FROM MILK-BORNE DISEASES.

Mr. Nathan Strauss, of New York, stated that the old city of New York, now the Borough of Manhattan, had established a new record in the saving of the lives of babies. Notwithstanding unusually severe periods of intensely hot weather the past summer, there had been fewer deaths of children under five years than in any preceding summer, and for the first time in the history of the city the summer mortality had fallen to a rate less than 50 per thousand per annum. When he first undertook to protect the babies of New York from milk-borne diseases by supplying pasteurised modified milk, in 1892, the summer saw the dying of 6,612 children under five years, making a rate per thousand per annum 136.1. With the steadily increasing use of pasteurized milk there had been a steady decline in infant mortality, until the summer just ended showed only 3,900 deaths in a population of children larger by 125,000 than that of 1892. In other words, in 1892, 964 children out of every 1,000 survived the summer, while in 1910 there were 988 who escaped death out of each thousand. In his practical experience the saving of children from milk-borne diseases warranted the assertion that the pasteurization of milk supplies of our cities, under careful health department supervision, would infallibly reduce the number of cases of infectious diseases and save lives of babies.

In no way could this Association save so many mothers from grief and loss of their little ones as by hastening the time when efficient pasteurization would be the rule, and when the milk-borne diseases would be as rare as the plagues that medical science had practically abolished.

At the general meeting of the Association, which was open to the public, addresses of welcome were delivered on behalf of the city of Milwaukee by Hon. Emil Seidel, Mayor; on behalf of the State of Wisconsin, by Judge William J. Turner, and on behalf of the medical profession, by Dr. W. A. Batchelor.

The responses to these addresses of welcome were made on behalf of the United States by Dr. Richard Lewis, Raleigh, N. C.; on behalf of the Dominion of Canada by Dr. Frederick Montizambert, Director-General of Public Health, Ottawa, Canada; on behalf of the Republic of Mexico by Dr. Jesus E. Monjaras, Mexico City, Mexico, and on behalf of the Republic of Cuba by Dr. Frederic Torralbas, Havana, Cuba.

### THE PREVENTION OF MENTAL DEFECTS AND MENTAL DISEASES.

There was a symposium on this subject.

Dr. William A. White, Washington, D. C., discussed the preventive principles in the field of mental medicine. The practical things that might be done at once in any community were these: "(1) The securing of legislation that places the responsibility for the care of the insane previous to commitment in the local health office. (2) Every city of one hundred thousand inhabitants or over to have a psychopathic ward connected with its municipal hospital, which is as accessible for the mental case as the other wards are for general medical and surgical cases. This ward should have an out-patient department. (3) The organization of an after-care society to assist persons who have been discharged from a hospital for the insane to get on their feet and to point out to them ways of avoiding the conditions which led to their breakdown. (4) The passage of adequate laws for the control of the labor of women and children. (5) Popular education. By the use of this term I am not merely dealing in a glittering generality that may mean nothing or everything. We have in this country nearly two hundred state hospitals for the care of the insane. These hospitals, each one of them, should be a center of information for the community in which it exists, and its medical officers should use their position to spread information about mental disorders. The superintendent, or a member of the staff, should deliver one or more popular lectures each winter to which the public are invited. Much might be accomplished in this way if all hospitals would do this. (6) Field work from the state hospitals and psychopathic wards as centers to study conditions under which insanity has developed, to furnish assistance to the hospital in dealing with its patients, and to co-operate with the after-care society. (7) More liberal support by city and state of scientific research work in this field, especially along the lines of etiology and prophylaxis.

### THE PREVENTION OF FEEBLEMINDEDNESS.

Dr. E. R. Johnstone, of Vineland, N. J., stated two or three states had passed laws authorizing the unsexing of certain degenerates after they get in institutions, but please note they had to get in the institutions first. He heartily approved of the operation of castration and merely agreed to vasectomy and oophorectomy for want of something better, for after these operations had been performed a fair percentage of the cases might be returned with safety to their homes and thus make room for others in the institutions, but the ideal way was to gather all of the feebleminded into institutions and train them in so far as possible to be self-supporting; plenty of industrial occupation and very little academic training. Thirty to fifty per cent could be made entirely self-supporting after ten years' training. Take the women of childbearing age first and teach them to raise and can small fruits, raise poultry and garden truck, knit underwear, weave rugs, carpets, etc. Then take the others as young as possible, and the economic problem came close to solution. He stated they should not talk, but get to work. The numbers were increasing. If they did not

care for them in well-conducted training schools where they might learn to contribute toward their own support, they must keep them in almshouses, reformatories, prisons and other institutions, and when they were led into evil ways, they had to pay for these patients' arrest, their trial and the damage they had done. If feeblemindedness was to be checked, they personally must do something.

### PREVENTABLE NEUROSES.

DR. C. H. HUGHES, of St. Louis, Mo., stated they had heard a good deal of late about the conservation of forests, which had been a subject of national concern, but what he wished to speak about was the prevention of the neuroses which underlay the physical, the moral and the mental integrity of the people, and which, if not considered and timely regarded, would eventuate in degeneration and degradation of their people, such as have visited the people who had gone before. The neuroses constituted the bane of civilization. It was the neglect to care for a neurosis that caused the greatest of human generals to fall. It was an epileptoid condition, which was neglected, that caused Napoleon Bonaparte to lose the battle of Waterloo. They were for prevention of the neuroses, those conditions of mind and of the nerve centers otherwise that had so much to do with the individual in the community, with the individual on the firing line in the battle of life, and with the individual who had to meet the duties and obligations of their modern civilization, with its strenuous demands; and it was in the prevention of the neuroses, beginning with the cradle and extending up to manhood and through manhood, they had most to do as physicians who wished to conserve the vitality of their race and save America. They must take care of the neuroses because they were the bane of civilization; they were the bane of the family life; they were the bane of the social life. The incongruities and unhappiness that existed in families and revealed so largely in the divorce courts were the product on one side or the other, and oftentimes on both, of the dominance of the neuropathic element in one or the other or both members of the family, and they were called misfits. They were called incompatibilities by lawyers, who could not find a better term, but they were conditions of neurotic ill-adaptability. They were physical misfits. What he meant by the neuroses was not alone functional conditions of the nervous system, because the line of demarcation between functional and organic disease was only a question of time and of study and further observation, but the functional affections of yesterday were the organic troubles of to-day. The time was coming when they would understand hysteria to be an organic disease. Insanity came down to them in its predisposing element in the majority of instances as an inherent predilection, an inherent organic tendency, and superadded to it came the disturbance or influence of environment, the disturbing influences of depressive passion, the influences of conditions of overstrain, overworry, which over-annoy the human mind. They should have a reasonable regard for the powers of the growing child, so that he might not be overstrained. He should have an adequate amount of fresh air, abundant nutrition, ample time for rest, and the prevention of those conditions which came from excesses was the cardinal principle which underlay the prevention and evolution and final destructive development of all neuroses.

### DISCUSSION.

DR. JOHN N. HURTY, of Indianapolis, Ind., stated that if they did save a child from diphtheria or scarlet fever and yet failed to save it from some neurosis, the child was lost just the same. The longer he lived and worked in the science of hygiene, the more he was convinced that there was no hope to work with the adult. They must go back and instruct the child. That being done, they had taken the first step. Under their present form of education they did not do that except to a limited degree. The thought was gradually penetrating their minds that the child must have playgrounds and fresh air. They have been shutting out the air from the schoolroom and calling it economy. They had been buying sites for schoolhouses without playgrounds, and calling that economy, and it was the worst kind of extravagance. Something must be done to prevent the building of insane asylums, taxing the people, raising the rates, and having insane on every hand, and the way to do that was to begin with the child.

DR. HENRY A. NORDEN, of Sturgeon Bay, Wis., stated that, aside from trying to make a living in the practice of medicine, he had been riding a hobby — the education of children. Neurotic conditions were superinduced by night studies on the part of children. He stated you should not blame the teachers; should not blame the school board, but blame the people who were behind them and have them prevent the school board from doing what they should do. It was absolutely necessary, considering the way education was carried on to-day, for the child to study at night or to sacrifice the playtime of the day. It was almost impossible for children to study in school with one section of the schoolroom reciting. He had suggested frequently in his work to cut down the number of hours of school sessions; that they use the school session for the recitations and explanations, and allow a part of the day to be used for pleasure and part for study. In that way they could prevent neurotic conditions that were produced by night studies.

DR. E. C. ROGERS, of Fairbault, Minn., stated wherever there was a family with two feebleminded children, that family ought to be studied carefully, its ancestry gone into and the mental condition of these children studied carefully, and from the work that was now being carried on they hoped to have data which would give them the facts necessary to make statements as to what should be done towards prevention.

### PRESIDENT'S ADDRESS.

DR. CHARLES O. PROBST, of Columbus, Ohio, stated a renaissance in health was at hand. Never before had the public shown such interest and enthusiasm in health measures. Never had it so nearly reached a realization of the immense possibilities in preventing sickness and prolonging life. The time was ripe for co-operation of the widest sort. Without attempting to even outline a plan for co-operation, he recommended that by committee or otherwise the question be investigated of the possibility of uniting or concentrating the efforts of the different national organizations in the four countries represented whose work concerned in any large measure the promotion of the public health. If moral prophylaxis came within the scope of social hygiene, the question of providing suitable amusement for the working people became of greatly increased importance. Especially was this true for working girls. The lack of such places in large cities was among the chief causes of the social diseases. The department of child hygiene of the Russell Sage Foundation, established in 1908, occupied a part of this field. Its purpose in part was to conduct researches and promote activities favorable to the physical, moral and intellectual welfare of children, especially public recreation, and the health and progress of school children. This association stood for the highest possible standards in public health. In various ways it had given weighty support to many

health movements for improving general health conditions, and notably in the interest of pure food and the establishment of a national health department. The family physician must long remain the chief instructor and most potent factor in preventing the spread of dangerous infectious diseases. The strongest nation, the one of greatest achievements, would in the end be the one that gave the greatest amount of intelligent care to the health of its subjects. Eventually all health interests should be administered by the government. If the first step towards the centralization, or at least the co-operation, of the many associations devoted to health problems could be taken at the meeting, it might be the means of hastening the day when every individual would be given time and opportunity for the pursuit of health and happiness, and the certain knowledge of how and where to find them.

### ORGANIZATION OF THE PENNSYLVANIA STATE DEPARTMENT OF HEALTH.

Dr. Samuel G. Dixon, Harrisburg, Pa., said from July 22, 1907, to June 30, 1910, 32,347 poor tuberculous sufferers had received the skilled medical aid and the attention of trained nurses which the department's one hundred and fifteen dispensaries provided. The death-rate from tuberculosis in Pennsylvania had fallen from 134 to 120 per one hundred thousand of population in four years. This meant a saving of 1,000 lives annually. From October, 1905, when the state began its free distribution of diphtheria antitoxin among the poor, down to Dec. 3, 1909, 20,794 cases of this dread disease, mostly little children, were treated with the life-saving serum. They knew by statistics that without antitoxin 42 out of every 100 of these children would probably have died, but with the aid of the state's antitoxin the death-rate among these poor little sufferers was reduced to 8.48. Free antitoxin was also given in 15,125 cases, mostly children, who had been in contact with the disease. All but a very few of these were absolutely protected against diphtheria. A very low estimate of the saving of child life resulting from the state's free distribution of diphtheria antitoxin since 1905 was about 8,000 lives, a pretty good investment of the taxpayer's money. And what of typhoid fever in view of all this work for pure water? In 1906, 56.5 out of every 100,000 people died from this disease; in 1907, 50.3; in 1908, 34.4; and in 1909, 23.9. That is, there were now living 2,363 people who, had the death-rate of 1906 prevailed in 1909, would have died from typhoid. In 1906 and 1907, the death-rate in Pennsylvania per 1,000 of population was 16.5; in 1908, it had dropped to 15.7 and in 1909 to 15.3.

### REPORT OF COMMITTEE ON EDUCATION OF THE PUBLIC AS TO THE COMMUNICABILITY AND PREVENTION OF GONORRHEA AND SYPHILIS.

This report was presented by the chairman, Dr. George M. Kober, of Washington, D. C. The report contained several recommendations, which were referred to the Executive Committee for consideration, and which were reported back to the general meeting subsequently in the following amended form: The committee recommended: "(1) The recognition, study and control of the prevalence of these, as with all other communicable preventable diseases, in order to ascertain the distribution of them. (2) An educational campaign for parents of all social classes and children of all ages and sexes. This teaching should be not only moral, but also medical in the widest sense. (*a*) Proper distribution of circulars, pamphlets and other literature by state health department through all suitable channels. (*b*) State health departments to instruct all its local health officers in sexual matters, and direct them to make a systematic effort to educate the people in their respective communities. (*c*) State health departments to make a definite and determined effort to awaken and interest the medical profession in this fight against venereal diseases. (*d*) State health departments to send out especially trained paid teachers and lecturers of their own, supported by exhibits and lantern slides, to address special meetings of parents, health officers, medical men, teachers and others in schools, colleges, churches, etc., on these and other preventable diseases. (*e*) State health departments to encourage the organization of local leagues or associations whose purpose shall be the support of and control of a crusade against the spread of all communicable diseases, said societies to include every profession and walk of life; to depend on philanthropists for necessary funds rather than upon paid subscriptions for financial support. (*f*) Health departments to interest and provide for the authorities having charge of the educational curriculum in public and in private schools: (1) By introduction of biology into the graded courses of all schools. (2) To provide instruction in sexual matters for students of the upper grades. (3) By special instruction to normal school students who are to become the instructors. To impress upon presidents, deans, preceptors and teachers the necessity of exercising their influence on students in reference to the communicability of syphilis and gonorrhea, and to inculcate a morale of protection among the college fraternities. (*g*) To utilize the public press for the proper occasional presentation of the subject, and to discourage the display of advertising matter which encourages the exposure to dangers in these diseases. (*h*) To utilize church clubs, fraternal societies, trade unions, women's clubs, and especially mother's clubs for instruction of parents. (*i*) Health departments to recommend the enactment of laws for (1) physical inspection and segregation of prostitutes; (2) notification and report (by number, if desired) of venereal cases; (3) physical examination of men before marriage, male applicants for marriage license being required to obtain same to submit to an examination by a duly qualified physician for the purpose of ascertaining whether said applicants are free from venereal diseases; (4) to make it a crime to spread any venereal disease; (5) keeping open free night dispensaries and maintenance of special dispensaries and hospitals for these diseases. (*j*) Advocacy of temperance on account of the relationship between alcoholism and venereal diseases. (*k*) Advocacy of personal cleanliness and venereal prophylaxis. (*l*) Advocacy of early marriage."

These recommendations were adopted.

### VENEREAL DISEASES AMONG SEAMEN OF THE MERCHANT MARINE.

Dr. J. W. Kerr, of Washington, D. C., stated there were treated 1,281,427 cases of sickness from all causes, or an average of 53,392 patients annually. Of the total number, 106,090 were cases of syphilis in one of the three states, 4,420 being the annual average; 117,336 cases of gonorrhea (including gleet), representing an annual average of 4,889 cases; and 39,819 were cases of chancroid (including ulcer of the genitals), or an average annually of 1,569 cases. The total number of venereal cases treated and classified as above during the period mentioned was 263,245, or an average annually of 10,969 cases. It would thus be seen that these venereal cases represented 20.5% of the total cases treated. This percentage it would be understood represented cases of syphilis, gonorrhea and chancroid, and did not include complications or sequalæ of those diseases.

Dr. J. R. Kean, of Washington, D. C., made a

plea for applying the usual methods of preventive medicine to venereal diseases, and, among other things, said he did not think it was either wise or necessary for scientific men interested in the good of the race and of the country to take any part in the discussion of the relation of this evil to society. It was sufficient for them to know the following facts, that the prostitute was a present confrontation of the problem. There was no reason to think that these diseases were beyond the reach of preventive medicine any more than other contagious diseases, and their immunity from restriction must be attributed to the public disinclination to discuss them and legislate concerning them. He hoped that this association would not be deterred by the outcry of certain classes of persons who were accustomed to think with their emotions rather than their brains, from taking the bold stand in this matter which was justified by science, by common sense, and by the demands of the public good.

*(To be continued.)*

## Book Reviews.

*Pneumonia.* A Symposium on the Occurrence, Etiology, Diagnosis, Prognosis and Treatment of Pneumonia. Reprinted from *American Medicine*, April, 1910. Arranged and edited by H. EDWIN LEWIS, M.D. Pp. 182. Published by American Medical Publishing Company, 84 William Street, New York City. 1910.

The articles collected in this volume have already received sufficient attention in the reviews of current literature.

*The Practice of Medicine.* A Guide to the Nature, Discrimination and Management of Disease. By A. O. J. KELLY, M.D., Assistant Professor of Medicine, University of Pennsylvania; Professor of Medicine, University of Vermont. Octavo. Pp. 949. Illustrated. Philadelphia and New York: Lea & Febiger. 1910.

Kelly's "Practice of Medicine" is a valuable addition to our didactic literature. The author has aimed in it to prepare for the student and the junior practitioner the essentials of the subject, unadorned with great detail. In this aim he has been eminently successful. The volume presents a description of practically every known disease, with a terse but adequate discussion of each, well planned to impart with little effort on the part of the reader a clear view of modern medical knowledge. It deserves to be widely used both as a textbook by students and as a handbook for quick reference by the practitioner. The medical investigator may regret the absence of historical considerations and of mention of original work upon which its teachings are based, but these could only be introduced at a sacrifice of that conciseness which is one of the volume's most conspicuous merits. The student and the general practitioner will find included in its pages without consulting other works descriptions and directions for treatment sufficient for the purposes of practical medicine.

THE BOSTON
# Medical and Surgical Journal.

THURSDAY, JANUARY 12, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*Remittance should be made by money order, draft or registered letter payable to*

W. M. LEONARD,
101 TREMONT STREET, BOSTON, MASS.

## THE VANISHING BIRTH-RATE OF CIVILIZATION.

AGAIN and again the topic of declining birth-rates in civilized countries rises like a horrid specter to afford prophets of evil a welcome occasion to utter their dismal forebodings. It is perfectly true that at present the birth-rate among highly cultivated peoples, as among all highly evolved forms of life, is low and has for some time been falling. In France it is now only 20.1 per 1,000 of population, less even than the death-rate. In England it has fallen during the past thirty years from 35.4 to 26.6. In New England the birth-rate among native Yankees is already lower than the death-rate, as in France. On the basis of these and similar figures, Prof. Walter F. Wilcox, of Cornell University, at a meeting of the American Statistical Association in St. Louis during the last week of December, made the startling prognostication that in 2015 the total birth-rate in the United States will have fallen to zero. This important statement, if true, would mean the practical extinction of the race by 2100. Extermination is not a pleasant prospect; still, worse things might befall us, and we can at least go down as couragously as the crew of the *Royal George*. If the earth is soon to become as desolately frigid an abode as Dr. Wiley has been describing of late, perhaps the declining birth-rate is a merciful provision of nature for the anesthetic anticipation of our end. Who would wish his children to reap their food and steam-heat from wind-mills and storage batteries, only to perish at last of Arctic cold under an ice-bound Equator? But of course Professor Wilcox's prophecy is not to be taken, and probably was not intended seriously. It may be mathematically correct

(though even here it should seem that the professor had followed arithmetic rather than geometric progression), but it is not humanly true. Perhaps in these days of intense competition among the higher professions, a declining birth-rate may prevent glutting of the market by over-production. Howbeit, even though the birth-rate of civilization seem to be approaching a vanishing-point, it will at least approach that point at an infinitely decreasing speed. There will be an irreducible minimum beyond which the birth-rate, like the incidence of preventable disease, will not fall. It is probably safe to assert that until time makes this terrestrial sphere uninhabitable there will continue to be occupation for the obstetrician and for other physicians.

## DEATH-RATES IN BOSTON AND ELSEWHERE.

There has been of late from various sources considerable discussion of mortality statistics in Boston and other large cities, with comparisons, some favorable, some invidious. It appears that in 1910 both the total and the infantile mortality in Boston were higher than in 1909. The precise reason for this is not apparent, but the fact is in no sense disquieting or indicative of any hygienic or medical backsliding. It must be remembered that the death-rate of 1909 was exceptionally low, the lowest on record in the city. The total death-rate in Boston in 1907 was 18.74 per thousand of population; in 1908 it was 18.40; in 1909, only 16.88. So marked a fall was mathematically certain to be followed by a slight compensatory rise. No declining curve falls steadily without slight oscillations. Moreover, many factors besides disease incidence enter into the determination of the death-rate. One of the most important of these is the racial composition of a community. From a comparison of large numbers of statistics it appears that in our Northern states negroes show the highest percentage of mortality, Italians the next, and the Irish the next; whereas Scandinavians, the Scotch, Russians and Poles have the lowest relative mortality. The proportionately high percentage of Irish, Italians and Ethiopians in the population of Boston, though it would hardly affect the death-rate from year to year, serves to keep that rate higher than in some large cities with a relatively greater proportion of Teutonic and Slavic inhabitants. Boston has no cause to be ashamed of its death-rate, which we may safely expect to show a progressive though diminishing and not always constant decline in years to come.

## TERMINATION OF THE TYPHOID EPIDEMIC AT ANNAPOLIS.

During the past fortnight there have been no fresh cases of typhoid fever in the United States Naval Academy at Annapolis, Md., and the epidemic is now considered at an end. There have been no deaths, and the prognosis of those now convalescent from the disease is excellent. It is encouraging to note that during the course of the epidemic 200 cadets consented voluntarily to receive antityphoid inoculation as a protective measure.

In this connection it may also be recorded that General Wood, chief of staff of the United States Army, has recently issued a general order "directing all commanding officers throughout the service to use their best efforts to induce officers and men in their commands, and all civilians connected with the army, to be inoculated with antityphoid vaccine." Compulsory inoculation is now required of all bodies of troops going into the field for maneuvers or practice marches when the supply of drinking water is unreliable. It is also required of all members of the hospital and army nurse corps. During the past year, among 12,000 persons thus inoculated in the army, there have been 3 cases of typhoid fever and no deaths. Among 50,000 soldiers not inoculated, there have been approximately 300 cases and 30 deaths.

## SOME LARGE BEQUESTS IN MEDICAL CHARITY.

During the past week several large bequests to medical charities in or near Boston have been publicly announced. Among the most interesting of these is one that has just become operative under the will of the late John Ashton, formerly a barber in Boston, who died in 1867. A sum, now amounting to $20,000, which ever since his death has been involved in trust funds and litigation, has just become available and goes to the Massachusetts General Hospital as beneficiary. The Massachusetts General Hospital also receives a further sum of $25,000, and the McLean Hospital at Waverley, Mass., $50,000, by the will

of the late Sarah A. Matchett, of Brookline, Mass., allowed in the Norfolk Probate Court at Dedham, Mass., on Jan. 3. On the death of several private beneficiaries of the same will, the principal of various trust funds under the estate, amounting to over $100,000, will also go to the McLean Hospital.

Among numerous public charitable bequests in the will of the late Mary Lothrop Peabody, of Milton, Mass., filed on Jan. 7 for probate in the Norfolk Probate Court at Dedham, Mass., is one of $50,000 to the Children's Hospital, Boston. The Convalescent Home of the same institution, at Wellesley Hills, Mass., is also given $50,000. The same will also contains bequests of $10,000 to St. Luke's Home for Convalescents, Boston; and $500 each to the North End and South End Diet Kitchens.

It is by the generous remembrance of such persons as these that the medical and other charities of Massachusetts are built up and enabled to maintain their beneficent efficiency.

## MEDICAL NOTES.

APPOINTMENT OF A VETERINARIAN. — Dr. Patrick H. Malowney, of Detroit, Mich., was last week appointed a veterinarian in the Boston City Health Department.

DEATH OF A FAT MAN. — Samuel Harvey, a barber, who died of cerebral hemorrhage last week at Carnegie, near Pittsburg, Pa., is said to have weighed 450 lb. and to have been the heaviest man in the United States.

A CENTENARIAN. — Mrs. Hettie Jenkins, a negress, who died last week at Lancaster, Pa., was locally reputed to have been born in 1793. She is said to have been thrice married and to have had, by her successive husbands, twenty-five children, of whom only one son survives her.

NEW MILK ORDINANCE IN CHICAGO. — Beginning with Jan. 1 of this year, there went into effect in Chicago a new ordinance requiring that every cow from which milk is obtained for the Chicago market must be annually tested with tuberculin. Failing this, the milk must be pasteurized before being offered for sale.

PROPOSED REORGANIZATION OF PUBLIC HEALTH SERVICE. — It is reported from Washington, D. C., that a bill has been introduced before the National House of Representatives to reorganize the United States Public Health and Marine-Hospital Service for the purpose of extending its activities and enlarging its importance.

A TUBERCULOSIS CARAVAN. — It is reported from Indiana that a party of fifty tuberculous persons in that state have organized a caravan, consisting of two automobiles and twelve vans, in which they purpose to make a tour of Kentucky, Tennessee, Virginia, the Carolinas, Georgia, Alabama and Mississippi, traveling by day and camping by night. This novel method for treating phthisis is intended to combine the advantages of open-air life with the benefits of climate and the pleasures of travel.

CHOLERA IN MADEIRA. — Report from Lisbon states that on Jan. 5, 600 more troops of the Sixth Portuguese Light Infantry were dispatched from that city to Funchal to enforce sanitary measures against Asiatic cholera in Madeira. It would seem that the methods adopted in dealing with the epidemic in this island were unnecessarily coercive. One may shrewdly suspect that the new government in Portugal is glad to seize this pretext for sending out of the country as many as possible of the soldiers supposedly loyal to the recently deposed monarchy.

### BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 3, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 62, scarlatina 36, typhoid fever 11, measles 58, smallpox 0, tuberculosis 55.

The death-rate of the reported deaths for the week ending Jan. 3, 1911, was 16.35.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Dec. 31, 1910, was 232, against 261 the corresponding week of last year, showing a decrease of 29 deaths, and making the death-rate for the week, 17.96. Of this number 116 were males and 116 were females; 228 were white and 4 colored; 139 were born in the United States, 92 in foreign countries and 1 unknown; 55 were of American parentage, 151 of foreign parentage and 26 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 51 cases and 4 deaths; scarlatina, 33 cases and 1 death; typhoid fever, 9 cases and 0 deaths; measles, 55 cases and 0 deaths; tuberculosis, 52 cases and 22 deaths; smallpox, 0 cases and 0

deaths. The deaths from pneumonia were 46, whooping cough 2, heart disease 32, bronchitis 3. There were 9 deaths from violent causes. The number of children who died under one year was 26; the number under five years, 43. The number of persons who died over sixty years of age was 74. The deaths in public institutions were 81. Cerebrospinal meningitis, 2 cases. Acute anterior poliomyelitis, 1 case.

Of the above infectious diseases the following were non-residents: Consumption, 1 case. Scarlet fever, 4 cases.

Deducting deaths of non-residents, the total is 208 and the death-rate is then 16.10.

Address before Boston Scientific Society. — At the meeting of the Boston Scientific Society on Jan. 10 of this week, Dr. B. L. Arms, of the Bacteriologic Laboratory of the Boston Board of Health, made an address on "Some of the Debts that Man Owes to the Animals."

Additional Appropriations for State Board of Health. — The Massachusetts State Board of Health has requested for the coming year additional appropriations of $3,000 for its food and drug department and $10,000 for the pursuance of its investigations in acute poliomyelitis.

Officers of Homœopathic Medical Society. — At the annual meeting of the Boston Homœopathic Medical Society, held in Boston last week, the following officers were elected for the ensuing year: President, Dr. Samuel H. Spaulding, of Boston; secretary, Dr. William A. Ham, of Dorchester; and treasurer, Dr. George D. Bliss, of Dorchester.

Convictions for Illegal Drug Sales. — In a special report made last week by the secretary of the New England Watch and Ward Society to the directors of that organization, it is stated that during the past fifteen months the society has secured before the courts 109 convictions for illegal sale of cocaine, morphine and opium, principally in Boston.

Suit for Imperfect Extraction of a Tooth. — The widow of a recently deceased dentist in Lynn, Mass., has been sued for $1,000 by a former patient of her husband for pain and expense alleged to have been suffered because the latter failed to remove the whole of an aching molar tooth from the plaintiff's jaw. Such post-mortem litigation is depressing evidence of the fact that a physician's liabilities do not terminate even with his death.

Women as Centenarians. — According to recently published vital statistics of Massachusetts, 13 centenarians died in this state during the year 1909. It is interesting to note that all were women. The oldest is said to have been one hundred and eight. Four were natives of Massachusetts; 4 of Canada; there was 1 each from Rhode Island, Russia, the Cape Verde Islands and Ireland; and 1 whose birthplace was unknown. One of the 13 was single, 11 were widows, and 1 was survived by her husband. The moral of these figures, if any there be, seems to be that widows have a higher expectation of longevity than any other class in the community. Perhaps, however, the facts indicate rather a sort of selective fitness by adaptation, and that if a woman can survive matrimony she can survive anything.

## NEW YORK.

Bequests. — Among the charitable bequests in the will of the late Mrs. Charles W. Rockwell, widow of a New York banker, are the following: $10,000 each to the West Side Hospital and the West Side Sanitarium, and $5,000 to the Taylor Hospital, Scranton, Pa.; $3,000 to the Carbondale Hospital, and $2,500 to the Lebanon Hospital, New York.

Appointment of Dental Consultants. — Drs. H. L. Wheeler, of New York, and W. A. White, of Phelps, Ontario County, have been appointed dental consultants and special lecturers on oral hygiene of the New York State Department of Health. They will give public lectures on the prevention of tooth decay and will consult with local health boards and school authorities on the inspection of the teeth of public school children and the establishment of free dental clinics.

A Centenarian. — Mrs. Abbie Bingham, a negress, of Brooklyn, N. Y., died at the home of a granddaughter on Dec. 23, at the alleged age of more than one hundred and thirteen years, it being stated that she was born on a plantation near Norfolk, Va., on March 5, 1797. Her first husband, by whom she had one daughter, was, like herself, a slave. By her second husband, who died about twenty-five years ago, she had nine children, and of these, only three survive her.

County Hospitals for Tuberculosis. — It is reported from Albany that the boards of supervisors in the various counties of the state

are rapidly establishing county hospitals for tuberculosis, fourteen counties being already supplied with such institutions. In some instances the supervisors avail themselves of facilities which have been previously provided in the county. Thus, Dutchess County is cooperating with the city of Poughkeepsie, and Chemung sends its cases to the Elmira tuberculosis hospital.

MEETING OF SOCIETY OF DIRECTORS OF PHYSICAL EDUCATION. — The fourteenth annual meeting of the Society of Directors of Physical Education in Colleges was held at Columbia University on Dec. 30 and 31, a gathering in which nearly all the principal colleges in the country were represented. Dr. A. Alonzo Stagg, of Chicago, presided, and there were many interesting papers and discussions.

CAMPAIGN AGAINST HOOKWORM DISEASE. — Major Bailey K. Ashford, who since 1908 has been in charge of the Marine Hospital at San Juan, Porto Rico, and whose work against the hookworm disease has attracted national attention, arrived from San Juan on the steamer *Caracas* on Dec. 26. He states that the fight against uncinariasis in Porto Rico was going on in Porto Rico long before the discovery of the disease in the South. Since 1904 there have been 300,000 cases on the island. The campaign against the disease began at Bayamon, where a hospital was opened, but this was afterwards removed to Utuado, which was situated in the worst district. With the limited means supplied, much good was accomplished, but the work received a setback in 1908, when the legislature did not appropriate any funds and a number of dispensaries had to be closed. Since then there has been a gradual improvement in the situation, and foremost in the fight has been Dr. Pedro G. Igaravidez, director of the Service of Tropical and Transmissible Diseases of Porto Rico. "Now," says Major Ashford, "we are well equipped, and our success in combating the disease is very great. This has been accomplished without the help of men of means. At present, conditions in Porto Rico are good, and health and sanitary conditions are of the best."

ROOSEVELT HOSPITAL AND THE COLLEGE OF PHYSICIANS AND SURGEONS. — Dr. Samuel W. Lambert, dean of the Columbia University Medical School, is authority for the statement that there is to be no change in the relations between the school and Roosevelt Hospital on account of the recently announced alliance with the Presbyterian Hospital, although of late years these relations have been growing less and less close. At present there is only one professor of the faculty who is connected with the hospital, although there are still on the staff several officers of lesser rank. Dr. Lambert also states that there is no present intention of giving up the buildings of the College of Physicians and Surgeons, which are located across the street from Roosevelt Hospital. Some time ago a site for a new medical school was purchased in the immediate vicinity of the main buildings of Columbia University, but as that was before the alliance with the Presbyterian Hospital was contemplated, it is the general impression that the new buildings, whenever it is decided to erect them, will be somewhere near that hospital.

MORTALITY. — The weekly reports of the Health Department show that in the month of December the mortality in the city represented an annual death-rate of 17.27, as against 13.87 in November and 17.31 in December, 1909. The corrected death-rate, excluding non-residents and infants under one week old, was 16.28. Among the diseases in which there was an augmented fatality were the following: The weekly average of deaths from scarlet fever increased from 5 in November to 9.75 in December; the weekly average from whooping cough, from 4.25 to 5.75; from influenza, from 3.25 to 22; from epidemic cerebrospinal meningitis, from 2.75 to 6.75; from pulmonary tuberculosis, from 155 to 166.75; from acute bronchitis, from 19.5 to 23.75; from pneumonia, from 94.5 to 185.75; from bronchopneumonia, from 73.5 to 109.75; from organic heart diseases, from 137 to 178.25; from appendicitis and typhlitis, from 8.25 to 11.75; from cirrhosis of the liver, from 16.5 to 27.5; from Bright's disease and acute nephritis, from 108.25 to 120.25; and from puerperal diseases, including septicemia, from 8.75 to 13.25. Both influenza and pneumonia are more prevalent than at this time last year. In the week ending Dec. 24, there was a sudden increase in the deaths from influenza, from 9 in the previous week to 34, while the rise in the mortality from pneumonia has been more gradual. Among the few diseases in which there was a diminished fatality are the following: The weekly average of deaths from typhoid fever declined from 15.25 to 12.25; from diarrheal diseases, from 65.5 to 42.25; from diarrheals under five years of age, from 57.5 to

36.25; from cancer, from 70 to 67.25; and from apoplexy and softening of the brain, from 25.5 to 23.

Free Clinic for Animals. — The New York Women's League for Animals, which was formerly the Woman's Auxiliary of the American Society for the Prevention of Cruelty to Animals, has received a gift from Mrs. Russell Sage of $1,500, which is to be applied to the maintenance of the League's Free Clinic and Dispensary for Animals. This clinic has been in existence for a year, and at it the sick and injured horses, dogs and cats of the poor are treated.

Deaths by Violence in the Streets. — The National Highways Protective Association reports that in the streets of New York, in the year 1910, 376 persons were killed and 930 injured by vehicular traffic. One hundred and fifty-eight of the deaths were due to horse-drawn vehicles, 114 to trolleys and 104 to automobiles. More than half of the persons killed by all sorts of vehicles were children under fourteen years of age, and not more than 40% of these were killed by their own fault.

A Check to Scientific Progress. — The present commissioner of public charities, M. J. Drummond, appears to be a different sort of a man from his predecessor, Mr. Hebberd, who always gave the most enlightened aid to the physicians connected with his department. During the administration of the latter, through the liberality of Mrs. Russell Sage, the Russell Sage Institute of Pathology was established on Blackwell's Island, with an income of $12,000 for the maintenance of its laboratory work. The directors of the institute were Drs. E. G. and Theodore Janeway, Simon Flexner and D. Bryson Delavan and Prof. Graham Lusk, of Cornell University, and Commissioner Hebberd appointed as members of the Scientific Advisory Council of the institute a number of the most distinguished physicians of the city. During their incumbency, the directors of the institute state, their relations with the department resulted in complete co-operation, "which reflected itself in advance in all that made for the good of the city institutions in question, and consequently satisfied the officers of the institute." Shortly after Commissioner Drummond took office, however, these gentlemen were removed and an advisory board appointed which consisted largely of laymen with no scientific knowledge whatever. On account of increasing friction with the present commissioner, whose attitude towards scientific research appears to have been distinctly inimical, and whom he accuses of political methods, Dr. Theodore Janeway, who for some years has been on the medical board of the City Hospital, Blackwell's Island, and who was largely instrumental in inducing Mrs. Sage to donate $300,000 for the establishment and maintenance of the institute, has now resigned from the hospital; and Mr. Drummond has issued an order that, in so far as the institute acts as a city laboratory, its work shall be placed under the supervision of the medical board of the City Hospital. He has also designated a committee, composed of three of this board, to confer with the trustees of the Russell Sage Institute of Pathology, "with the idea of continuing the future pathological work of the institute under such conditions as will be satisfactory to all concerned." What action the authorities of the institute will take regarding this order remains to be seen.

2. Gottheil's conclusions from a limited experience with arsenobenzol are not as enthusiastic as those of many writers. He finds that its immediate effect may be better in some cases than that of mercury. It must be used with care because of its possible bad effect on the kidneys. It should never be given in office practice; the patient should be carefully examined before it is administered and should remain in bed under observation for several days after. It is indicated in especially severe and malignant cases, in cases where mercury has failed, and in other instances in which there are reasons for unusual antiluetic measures. [L. D. C.]

1. Butler considers that the "habitus enteroptoticus" is a congenital or hereditary and not an acquired anomaly in children. Cases of the acquired type are extremely rare. This habitus is more frequent in females. No one sign, such as a fluctuating tenth rib or a narrow epigastric angle, can be depended on to decide the existence of the habitus enteroptoticus in a child at any age. It is the whole picture of the slender body, frail bony structure, thin musculature, long narrow chest and the slightly bulging abdomen that makes the classification and makes it possible to recognize this type early enough in life to institute proper methods for its amelioration.

4. Eisendrath and Strauss, in experiments on rabbits, find that temporary compression of the renal vessels, if continued thirty minutes or less, causes very slight changes in the kidney, but if continued forty-five minutes causes considerable parenchymatous degeneration and interstitial infiltration, and if continued one hour or longer causes marked permanent degenerative changes in the whole organ. [E. H. R.]

3. Mayo has found that great advantage occurs by the ligation of the vessels, nerves and lymphatics at the upper pole of the thyroid in mild cases of hyperthyroidism and in those seen early. This procedure often brings about a reversion of the disease to its simplest form. This same treatment is indicated in more advanced cases in which changes in the heart, liver, etc., have become serious. In this group improvement is generally very marked and often so favorable that the secondary removal of the larger lobe can later be effected with greater safety.

8. DaCosta's very interesting article emphasizes the following points: Post-operative insanity is more common in women than in men, and less common in children than in adults. A trivial surgical procedure is just as likely to be causal as a mutilating operation. A brain operation may seriously damage the brain, but in spite of this is seldom followed by insanity. The removal of ovaries or testes deprives the system of an accustomed internal secretion and is more liable to be followed by insanity. In all cases of post-operative insanity there is predisposition, hereditary or acquired. The operation constitutes only an exciting cause acting on a predisposed nervous system. Such individuals were in danger of insanity before the operation was performed and would have probably gone insane anyhow sooner or later had some other exciting cause, other than the operation, arisen. A normal, stable, healthy brain will probably never go insane after an operation unless that operation attack the brain, the ovaries or the testes. Insanity that comes on immediately after an operation is probably due to the anesthetic. There is no special mental condition characteristic of post-operative insanity. The commonest condition is acute confusional insanity. Prolonged or acute worry before operation is a very common antecedent of post-operative insanity. This condition is practically identical in nature and mode of genesis with puerperal insanity. Septic cases, other things being equal, are more liable to go insane than clean cases.

10. Hill believes that the use of the extract of corpora lutea in 5-gr. doses three times a day is decidedly beneficial in the artificial menopause due to operation. The severe nervousness is completely relieved and the insomnia lessened in many cases. The extract is harmless, but gives no results in the natural menopause. It is deserving of further investigation. [E. H. R.]

1. Latham contributes an interesting article on the treatment of bronchitis with vaccines. He describes the isolation of the infecting organism from the sputum, the preparation of the vaccine and its administration. Where one organism greatly predominates this is not difficult; where there are several organisms, however, it is best to try one vaccine after another until the proper one is found. He does not believe that the preparation of a polyvalent vaccine can be recommended as a scientific method. (It might, however, be better and far less expensive for the patient.) He gives the details of several illustrative cases. The dose of the vaccine and the

interval between doses are to be judged by clinical symptoms. The object is not to cause any marked reaction, but to continue with increasingly larger doses as long as improvement occurs. It is best to begin with a very small initial dose. Careful clinical records are necessary. The duration of a course of vaccine varies in the individual case.

2. Shaw presents an admirable and clear exposition of the present status of the vaccine treatment of pulmonary tuberculosis. He quotes extensively from German, English and American authorities. The paper is an excellent one and well worth reading by those interested in this subject.

3. Von Offenheim, in a general article, discusses vaccine therapy, its limitations, the opsonic index and its value, and the various methods of administering vaccines. The paper seems to be an open and fair-minded statement of this much-disputed subject.

5. This lengthy paper is largely a detailed discussion of the diagnosis, differential diagnosis, symptomatology and treatment of scarlet fever.

6. Kirkland contributes a lengthy article in which he attempts to cover the entire subject of gallstones and the surgery of this condition. [J. B. H.]

8. In this number of the journal there are several articles on the results of the use of Ehrlich's preparation "606." This article summarises the points which it is well for the general practitioner to know about the preparation. The preparation is now made under the personal supervision of Professor Ehrlich at one factory under the name of Salvarsan. It is a clear golden powder which contains 34% arsenic and when dissolved in water has a strong acid reaction which must be neutralized before injection.

Its use is indicated in all stages of syphilis and in parasyphilitic diseases; also in other diseases known to be caused by spirilla and other parasites; also in a certain number of skin diseases of unknown etiology. It is contraindicated in advanced degeneration of the central nervous system, fetid bronchitis and in people with an idiosyncrasy against arsenic. Other constitutional diseases, such as diabetes, nephritis, etc., do not contra-indicate.

The dose is .01 gr. per kilo of body weight; for women, a slightly smaller dose. Smaller doses used several times are not as effective. It can be given subcutaneously, intravenously or intramuscularly. A description follows of the methods of preparing it for each injection. If the powder has lost its golden color or the ampulla is broken, letting in the air, it should not be used. [C. F., JR.]

1. Henkel reviews carefully the experimental work done on animals by injection of common salt. From this work some observers showed that salt in large quantities might be injurious. The writer then describes experiments upon humans to whom he gave salt in moderate doses by mouth, subcutaneously and intravenously. Some of the persons were healthy, several were pregnant and a few were convalescing from nephritis. The conclusions are that in no case was there evidence of injury to the kidney or to any other organ, and that convalescence of the nephritic patients was not unfavorably influenced. Diuresis was increased in some of the cases and not in others. Increase of specific gravity of the urine was noted in two cases. It is pointed out that by giving large quantities of weak salt solution, toxins of infection may be diluted and recovery thus promoted; but the writer does not make it clear whether he would prefer salt solution to plain water if water could be taken freely by mouth.

2. The writer discusses the experience of himself and others in the x-ray diagnosis of gastric ulcer and draws the conclusion that it is of little value for the diagnosis of fresh ulcer, but that indurated or perforated ulcers may be recognised by the changes which result in the neighborhood of the stomach, and that for gross secondary changes in the whole of the stomach the x-ray is particularly valuable. It is of value also for distinguishing between ulcer and cancer.

3. It is stated that urobilinuria in scarlet fever is the surest means of detecting parenchymatous hepatitis; and it is advised that tests for it should be made in all cases in view of the possibility that a chronic cirrhosis, analogous to chronic nephritis, may develop. [G. C. S.]

16. BLUMM, R. *The "Poison-box" of the Official Physician.*

1. The writers base their conclusions on 155 gynecological and obstetrical cases in which they have tried sacral anesthesia. They recommend the method of Gross and Läwen. Summarising, they say that on account of the difficulty of the technic, fat people are unsuitable subjects; that the procedure when well done has caused no serious untoward effects; that the method is applicable for gynecological operations on the external genitalia and for hemorrhoids and for obstetrical cases for repair of lacerations or forceps extraction; and that by this method,

in combination with scopolamin-morphin-sleep, sensitive individuals may be spared the pains of labor.

2. Hamm reports about twenty post-partum cases in which he observed the pulse-rate. He says that in about one case in ten there is a definite bradycardia which he believes to be due rather to vagus irritability than to myocardial change. He intends to pursue his study further.

3. Having had a large practical experience with the subject, Meyer says that as far as present knowledge shows, healthy persons may carry dysentery bacilli for three months, rarely for seven months; and that police supervision offers a practical way of fighting dysentery. Drug therapy has failed to expel the bacilli, but antiseptic precautions carried out after every stool minimize the danger. It is advisable that those who have had the disease should regulate their diet so as to prevent return of diarrhea, and should avoid exposure and fatigue. Bacilli may disappear from the stools for considerable periods and be found again later. Therefore the motions should be examined weekly even if they appear normal. Healthy people who have not had dysentery may for a time be carriers of the bacilli.

5. The writer reports a few cases and points out the fact that when children have been fed on Finkelstein's "albumen-milk" untoward effects may follow the subsequent administration of sugar. [G. C. S.]

BERLINER KLINISCHE WOCHENSCHRIFT. No. 48.

Nov. 28, 1910.

1. *COENEN, H. *Progress in the Pathogenesis and Treatment of Necrosis of the Pancreas.*
2. WOHLGEMUTH, J. *Pathological Action of Ferments.* (To be concluded.)

7. WOLFF-EISNER, A. *Concerning Non-Toxic Tuberculin.*
8. KLOTZ. *Experience concerning the Therapeutic Application of Bolus Alba and Carbonic Acid Snow.*
9. LIESKE, H. *Proposed Change in Legislation Relative to the Isolation of Persons for Observation of Their Mental Condition.*

1. The author points out the progress made in the treatment of pancreatitis and gives the results of early operation in Breslau under Köttner, where the mortality has dropped from 30% to 8%. He discusses at length the recent progress made in experimental work as to the origin of pancreatitis. Then follows a full description of five cases of necrosis of the pancreas. In conclusion he states that certain light attacks of this malady occur, and recoveries without treatment follow. He points out the necessity of drawing a distinction between the light, severe and chronic attacks. An early operation offers by far the best chance. We must pay greater attention to the earliest possible symptoms, which at present are far from being clearly and sharply defined. [J. L. H.]

## Miscellany.

### MEDICAL INSPECTION OF FACTORIES.

ONE of the topics for discussion at the fourth annual meeting of the American Association for Labor Legislation, St. Louis, Dec. 28–29, 1910, was, "Do We Need Medical Inspection of Factories?" Dr. William C. Hanson, of Boston, representing the Massachusetts State Board of Health, read the following paper, which was accepted without discussion: "Do We Need Medical Inspection of Factories?"

"For practical purposes, we shall understand factory inspection to include inspections and investigations of conditions affecting the health safety or welfare of persons engaged in industrial pursuits. Factory inspection includes a very large amount of work which can properly be designated only by the words 'factory hygiene,' which, used in the broader sense, includes the hygiene of occupation or the effect of industry upon health; and factory hygiene, in turn, must properly be considered a branch, but not an isolated part, of community hygiene.

"Opinions of some of the Massachusetts State Inspectors of Health, who have had nearly four years' practical experience:

"'The examination of the health of minors, and, whenever possible, of adults, can only be done by medical inspectors.

"'Medical inspection alone can insure progress in factory inspection and save it from mere routine.' — Dr. Harry Linenthal.

"'Any relaxation of medical inspection of workshops and factories would be a step backward.' — Dr. Lyman A. Jones.

"'The primary object, the health of the employee, should ever be kept in view rather than the mere detail of inspection.' — Dr. Wm. H. Coon.

"'Non-medical men, or inexperienced medical men, cannot cope with the many problems arising in connection with the work or deal successfully with well-trained mill men in industrial problems.' — Dr. Adam S. MacKnight.

"'The medical inspector is able to do all that the layman does, and his medical training enables him to do much that is necessary, from which the layman is barred.' — Dr. Wm. W. Walcott.

"'My medical training has been a help to me in that I more fully appreciate the injurious influences on health of poor ventilation, poor light, excessive heat and moisture, poisonous and irritating dusts, gases and fumes.' — Dr. Lewis Fish.

"'Much that I have learned about dangerous trades would never have been found out, or fully understood, without a medical teaching.

"'The possibilities of the spreading of infectious diseases by the various trades and customs are more readily seen by the man who knows something about the nature of the organism and its mode of action.' — Dr. Charles E. Simpson.

"'Three years' medical inspection work in factories have brought to light many grave and faulty hygienic conditions, which have been allowed to exist for years under the non-medical factory inspection system.

"'Hitherto non-recognized conditions of ill-health of minors have been found by medical inspection, as well as non-recognized cases of diseases dangerous to the public health among both minor and adult employees.' — Dr. Elliott Washburn."

Aside from such work as that which requires special technical knowledge, by far the most important part of factory inspection can be done only by well-trained physicians who have some practical knowledge of hygiene and sanitation. While it is obviously true that factory inspection by medical men exclusively is neither practicable nor economical, it is equally true that

medical men alone are in position to make the best use of facts obtained concerning the sanitary conditions of the premises where men and women work; to study the possible injurious effects of certain processes upon health of the persons engaged therein; to inspect devices designed to protect the employees against injurious and dangerous substances and to judge of the effects upon the health of operatives of such substances, as well as to detect pathological signs or symptoms of certain poisons, dusts and fumes incident to some occupations; to inquire as to the health of the employees, both for the purpose of aiding those found in ill health or physically unfit for work and for protecting others from infectious diseases; to make physical examinations of minors, and, whenever possible, of adults engaged in trades or occupations deemed to be injurious to health; and to collect and make proper use of all facts and data, including morbidity and mortality statistics, pertaining to occupational hygiene.

## BOYLSTON MEDICAL SOCIETY, 1811–1911.

The centennial anniversary of the Boylston Medical Society was celebrated by a dinner at the Harvard Union, Jan. 6. Some two hundred and fifty active and graduate members were present. The living room of the Union made a splendid setting for such a memorable occasion.

Dr. John Lovett Morse, president of the society, acted as toastmaster. In his introductory remarks he mentioned that this was probably the first time in America that an undergraduate medical society was able to celebrate its one hundredth anniversary. He stated that members from far distant states had written or telegraphed their regrets. He then introduced Dr. David William Cheever, professor of surgery, emeritus, in the Harvard Medical School. Dr. Cheever spoke of the society as he remembered it when an active member in 1854. The meeting place was the small and bare library of the Medical School on North Grove Street. He spoke of the medical instruction in those days and the quality of the students, and, in striking contrast to these, of the faculty, made up as it was in part of names immortal in the history of medicine. He told of the trials of the demonstrator of anatomy in the days before cold storage and antiseptics. In closing, he quoted timely advice from an address he delivered in the Medical School some forty years ago on the ideals and rewards of the medical practitioner.

The next speaker, Mr. Miles Fuller Porter, Jr., vice-president of the society, spoke with eloquence and force on what the Boylston meant to the undergraduate to-day and paid a fitting tribute to Dr. Morse and his influence on the society.

Dr. John Winters Brannan, chairman Board of Trustees of Bellevue and Allied Hospitals, was the next speaker. He told of his early association with the society and the life of the medical student of his day. He entered a plea for the better housing of the medical students and hoped that a comfortable dormitory would soon be added to the group of buildings on Longwood Avenue. He stated that a movement was already started in New York in connection with the Y. M. C. A. to provide the medical students with proper quarters. In conclusion, he mentioned that as opposed to corrupt politicians in his department in the city, he had the active support of six men, five of whom held degrees from Harvard University.

Dr. S. J. Mixter, of Boston, moved that a suitable telegram be sent on this occasion to a physician's wife in the South who was proud of her blood relationship to Nicholas Boylston, in whose honor the society was named.

The fourth speaker of the evening was Dr. Reginald Heber Fitz, professor of the theory and practice of physics, emeritus, of the Harvard Medical School. He told of the founding of the society and of the Boylston family and its contribution to medical education. He dwelt at length on the life of Zabdial Boylston, a colonial physician, and on his introduction of inoculation as a preventive measure in Boston, then in the throes of a smallpox epidemic. This was really the first great work of preventive medicine in America. He told of the opposition Boylston met with, of his persecution by the medical profession, of his courage and perseverance, and of his final recognition and fame.

The concluding speaker of the evening, Dr. Charles William Eliot, touched upon the Harvard Medical School as he knew it first in the early fifties, when he was instructor in chemistry. He contrasted the students of that day with those of the present classes. He spoke of the tremendous changes in instruction in the past thirty years, and stated that we must expect even greater changes and advance in the years to come. That the physician of the future would have much wider range for his activities was assured. He must treat classes of mankind and humanity in general for their woes rather than merely treating individuals.

Dr. Morse concluded the formal events of the evening by handing over the active management of the society to the members of the third-year class of the Harvard Medical School and the new president of the society, Dr. Edward H. Nichols.

## Correspondence.

### THE MEDICAL PROFESSION MUST CHANGE ITS TACTICS.

12 Mt. Morris Park, West,
New York, Jan. 5, 1911.

*Mr. Editor:* He who is not a frequent visitor to radical clubs, does not come in contact with newspaper men, with New Thoughters and who does not read regularly the numerous naturopathic, health culture and physical culture journals and other allegedly advanced publications can have no idea how the medical profession is ridiculed, how it is maligned, how it is lied about, how it is misrepresented, how it is "knocked" on every possible occasion.

We are pictured as ignoramuses, grafters, butchers,

anxious to operate whether there is a necessity or not, drug dopers, etc. We are denounced as a trust, monopoly, and any attempt of ours to organize, to pass laws protecting the public health, is characterized as an attempt at class legislation, a desire for special privileges, inspired by our fear of the competition, by our fear of the superior skill of our irregular rivals.

And the average physicain who has not given the matter any thought has no idea what effect these unceasing slanders and persistent lies have on the public mind, how suspiciously a large part of the public is beginning to look at the medical profession, how we are losing the confidence of the people, how the ground is slipping from under our feet.

As an illustration we need only mention the reception that has been accorded to the suggestion of a Federal Department of Health. The motives that actuate us and the objects of such a department were at once misrepresented; the people were made to believe that their freedom to choose a medical adviser was threatened; the forces of reaction and obscurantism, masquerading in some instances under the guise of liberalism, were quickly marshalled, and in a short time a society was organized, which now claims a membership of one hundred and fifty thousand.

We physicians are ourselves to blame. When the irregular, fantastic and pernicious cults began to make their appearance, we paid no attention to them. We thought they amounted to nothing, and would soon dry up and shrivel away of themselves. When the malicious attacks began to appear in the various quack publications we remained silent. We considered it *infra dignitatem* to pay attention to them, and we thought that the public would have no difficulty in seeing through their falsity and meretriciousness.

Our long and patient inactivity has been due to the false idea that truth will always triumph and error is bound to die. Yes, eventually. But if error is allowed to grow and spread unhampered, while those who see the truth will not take the trouble to proclaim it and expose the error, then it can take centuries before the correctness of the truth and the falsity of the error will be perceived.

In this as in every line of human activity prevention is immeasurably superior to cure, and the right way to fight error is not to permit it to get a firm foothold. Error and superstition are hard things to uproot after they have attained the dignity of a universal belief.

It is time that the medical profession change its tactics and assume a wide-awake, militant attitude. It is time that we actively attack error wherever it shows its head. By reading papers before lay audiences, by participating in discussions, by writing to the newspapers, by refuting the false arguments of the false prophets wherever they appear, we can do much toward destroying the influence of the quacks and the irregular cults. In short, we must throw off our exclusiveness, we must go out to the public and take it into our confidence.

The truth is with us — that we know; only we must not hide it under a bushel and expect that its light will, without any effort on our part, penetrate into the darkest recesses of ignorance and quackery.

Very truly yours,

WILLIAM J. ROBINSON, M.D.,
*President American Society of Medical Sociology*

## THE HEREDITY OF INSANITY.

BOSTON, Jan. 11, 1911.

*Mr. Editor:* In connection with investigations by the State Board of Insanity concerning heredity in mental disease, the question has arisen, *Does insanity in* BOTH *parents necessarily entail insanity in their offspring?* Any facts which our readers may care to offer in this direction will be gratefully received by the undersigned. Data should be included concerning the onset of the insanity in the parents, whether before or after the birth of the children, as well as concerning the age which the supposedly normal children have attained.

E. E. SOUTHARD, M.D.,
*Pathologist to the State Board of Insanity, State House, Boston.*

## SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY. — The thirteenth meeting will be held in Sprague Hall, Boston Medical Library, 8 The Fenway, on Saturday, Jan. 28, at 8.15 P.M. The following papers will be read: (1) "President's Address." (2) "When shall we Remove Tonsils and What shall we Do?" Eugene A. Crockett, M.D., Boston. (3) "What is to be the Attitude of the Pediatrist and the Orthopedist in the Treatment of the Child with Congenital Ptosis of the Abdominal Viscera?" Joel E. Goldthwait, M.D., Boston. (4) "Silver Nitrate Irrigations in the Treatment of Infectious Diarrhea in Infants." Richard M. Smith, M.D., Boston. Light refreshments will be served after the meeting.

JOHN LOVETT MORSE, M.D., *President.* FRITZ B. TALBOT, M.D., *Secretary.*

NEW ENGLAND HOSPITAL MEDICAL SOCIETY. — The annual meeting of the New England Hospital Medical Society will be held at the Hotel Vendome, Thursday, Jan. 19, 1911. Business meeting at 6 P.M. Election of officers and change of by-laws. Dinner at 6.30 P.M. An interesting program has been arranged by members of the Society.

BLANCHE A. DENIG, M.D., *Secretary.*

## RECENT DEATHS.

ROBERTS, OSCAR SAMUEL, M.D., M.M.S.S. died in Pittsfield, Jan. 4, 1911, aged seventy-three years.

DAVIS. SAMUEL ALONZO, M.D., M.M.S.S. (retired), died in Somerville, Jan. 3, 1911, aged seventy-three years.

DR. WILLIAM A. OBERLE, of Newark, N. J., died in the St. James's Hospital in that city, on Jan. 6, from septicemia contracted while operating on a patient. He was twenty-eight years of age and a graduate of the Baltimore Medical College.

DR. GEORGE BULL, an ophthalmologist, formerly of New York City, died on Jan. 1, in Paris, France.

DR. SAMUEL ALONZO DAVIS, who died of pneumonia last week in Boston, was born on Sept. 17, 1837, at Bridgton, Me. After graduating from Bridgton Academy, he entered the Harvard Medical School, from which he received the degree of M.D. in 1862. He practised for a short time in Charlestown, then joined the Thirtieth Massachusetts Regiment, which he served as surgeon till the close of the Civil War. Subsequently he resumed his practice in Charlestown, and continued it until his retirement in 1907. He is survived by his widow.

## Original Articles.

### THE SANATORIUM TREATMENT OF NEURASTHENIA AND THE NEED OF A COLONY-SANATORIUM FOR THE NERVOUS POOR.

BY FRANK K. HALLOCK, M.D., CROMWELL, CONN.

THE general principles underlying home, sanatorium and institutional treatment of neurasthenia and the psychoneuroses are essentially the same. The variations in the therapeutic procedure which may be attributed to residential conditions do not imply a change of these principles, but merely a difference in their application.

In neurasthenia and its associated disorders, psychasthenia, hysteria and hypochondria, we have presented, perhaps, the most comprehensive therapeutic problems in the whole range of medical practice. Speaking broadly, this class of disorders stands between the psychoses on the one side and the organic and severe functional derangements of the body on the other. That is to say, to a greater or less extent, the psychoneuroses constitute a blend or mixture of psychic and physical elements, and the entire individual requires treatment from every side. Whatever status is accorded these disorders, the main fact to note is that the fundamental principle of treatment requires the division of the therapeutic effort into two more or less parallel directions; one along the lines of the restoration of the bodily forces and the other along the lines of nervous and mental training. This doubly directed therapeutic effort represents a readjusting process, both mental and physical, and is educative in principle; that is, as far as possible the patient is taught how to help himself. That this idea or principle of teaching the patient is the correct one for the physician to hold is made evident by the fact that in the great majority of cases it is the kind and the way that the given life is led that makes the neurasthenic. Even when the original endowment of nervous energy is far below the average, as in the constitutional neurasthenic, the state of neurasthenia, barring intercurrent or accidental causes, could have been avoided if the individual had known how to use his limited amount of nervous energy.

Hence, in order to be able to hold the patient up to himself, as before a mirror, the physician must know the man even more than his symptoms; for, in a sense, these latter are merely the surface play of the deeper psychic and chemico-physiologic processes. To gain this knowledge requires the taking of a careful personal history and the making of a most thorough examination. All departments of the body organism, somatic, neurologic and psychic, should be inquired into, and of especial importance is the study of the circulatory system and the gastro-intestinal tract. In the last analysis the physical basis of neurasthenia lies in the biochemic processes having to do with the nutritional and metabolic functions of the body. This leads me to repeat a favorite dictum of mine which I have previously stated to this society, namely, that the integrity of the nervous system depends upon the integrity of the lower grade tissues of the body.[1] Conversely, the same holds true. Thus, using one word to explain the production of neurasthenia arising primarily from and through the psychological side, I should say that intensity, excessive or long continued, in the action of the nervous system, whatever else it may do, certainly tends to lead eventually to hypertension in the circulatory system, and this latter condition is the forerunner of all manner of ills.

After gaining sufficient knowledge of the patient, we proceed to follow out the twofold therapeutic effort. The first step is to formulate the best kind of a physical life for the patient to lead. The second step is to explain to him where he stands, what his symptoms mean, or, chiefly, what they do not mean; to teach him how to get out of his present condition and how to avoid a future breakdown.

The first step requires the laying out of a program for the daily conduct and disposition of time, including the employment of all curative agencies. These agencies may be classified as follows:

1. Natural: Air, sun, water, diet, rest, exercise, work, play.

2. Physical remedial methods: Massage, electricity, body manipulations by hands and by apparatus.

3. Medicinal agents: Symptomatic, metabolic.

The second step or division of the therapeutic effort relates to the nervous and mental training, and this means that we have to choose the kind of psychotherapy to be practiced.

One of the chief objections to the giving of suggestion by means of the various hypnotic procedures is that the changes effected in the patient represent something which is done for him. The miracle, so to speak, is wrought without conscious struggle, almost without his knowledge. The relief from pain or disagreeable thoughts is without credit to any effort on the individual's part; it is, as it were, handed him on a silver platter, and consequently he is not so likely to profit by his experience.

As already stated, the true therapeutic principle is educative; furthermore, it is the law of evolution that it is the fighting and putting forth of personal effort which makes the recovery more certain and more permanent. Hence, the ordinary conversational or, what I have elsewhere called the "plain talk method," is to be recommended for routine sanatorium practice.[2] This method may be defined as representing that class of educative-suggestive influences which result from explanatory and argumentative reasoning, appeal, advice or command, as exemplified in normal conversation of a deeply earnest and sincere character.

All psychotherapeutic methods which are intelligently adapted to the requirements of the individual and conscientiously practiced have their value, and they nearly all include a certain

[1] Proc. Conn. Med. Soc., 1907 and 1908.
[2] Psychotherapy. Edited by W. B. Parker, vol. ii, no. 4, 1909.

amount of psycho-analysis, the explanation of symptoms, the inculcation of hope and faith, and the teaching of the general philosophy of optimism. The appeal is made to change the viewpoint, to readjust the mental attitude so that the patient faces his problem with an earnest spirit of intelligent co-operation and a brave determination to succeed.

The *importance* of the psychotherapeutic side of the treatment of neurasthenia can hardly be overestimated. The *success* of the psychotherapeutic procedure will depend upon the personality of the physician combined with his psychological insight and the skill and wisdom of his suggestion and advice.

In comparing the relative merits of home, of a room with a nurse in a hotel or boarding house, of institutional and of sanatorium treatment, we may consider the following propositions:

First, during a course of treatment the neurasthenic patient is better off in a new environment. The change from the home conditions under which the neurasthenia developed to new scenes and different personal relations is almost invariably beneficial.

Second, by reason of the definite system under which they must be conducted, there exist in all well-regulated establishments certain institutional influences which operate silently, but more or less powerfully, upon the individual. One of the most important of these influences is that of resignation and obedience to general rules and a greater willingness to follow personal orders.

Third, other things being equal, the success and rapidity of improvement in the patient depends upon the ease and completeness with which all forms of treatment, physical and mental, can be carried on.

The third proposition is the chief and comprehensive requirement, and it is against this that the residential factor in the treatment of the patient has to be measured. When this is done it will be evident that the establishment representing the sanatorium principle is theoretically, at least, the best place for the neurasthenic invalid. Special neurological institutions or neurological wards in a general hospital stand next in order of preference, and within the limits of the city they offer the best provision for the poor neurasthenic.

When one considers the increased growth of nervous and mental disorders in present-day life, it is not too much to say that nearly every large general hospital should have both a neurologic and psychopathic department. While these departments should be specially equipped and conducted, they should, nevertheless, be regarded as divisions or branches of internal medicine.[3]

If a plan like this was more generally followed, three crying needs would largely be met. First, there would not be such a necessity for a special state institution for the temporary detention for observation of a person suspected to be insane, as was discussed by Judge Joseph E. Russell at the meeting of the Fairfield County Medical Association held in Stamford two days ago.[4] Second, the organization of a psychopathic department in general hospitals would tend to lessen the unfortunate stigma attached to both the insane person and the insane hospital. Third, the foundation of neurologic wards or departments in the hospital would certainly relieve in some measure the great demand for suitable places to send neurasthenic patients of limited means.

Returning to sanatorium treatment. Why is this superior to all other methods? It is because it best fulfills the conditions requisite for the perfect or ideal treatment of the neurasthenic. The establishment is a unit; it is located, planned, equipped and manned by medical officers and a corps of nurses especially trained for one single purpose. It is not a part of a larger, more comprehensive affair, like a general hospital. Being situated, as it should be, in the country and under conditions where the natural agencies have greater and more perfect play, it is superior to the city neurologic institute or hospital. The fresh air and unobstructed sunshine, the fields and woodland, the wide and pleasant view, the quiet and the freedom are assets of incalculable value.

There are, of course, various types of sanatoria, but nearly all of them fall between these two extremes: One is the sanatorium, usually the smaller, which is dominated by the spirit or influence of the head physician and upon whose personality and therapeutic skill chiefly depends the success of the institution; the other type is the sanatorium which relies more upon the application of various physical methods than upon the personal or psychotherapeutic ability of the medical officers.

Two widely known examples of sanatoria such as I have described are the institutions at Berne, Switzerland, and the Lahmann Sanatorium at Dresden, Germany. Professor Dubois at Berne hardly has more than a common bath-tub in the way of physical appliances. He depends almost entirely on psychotherapy. Dr. Lahmann, the founder of the Dresden institution, made it famous by his strong personality, but at the present time his successors rely almost entirely upon the use of physical methods and apparatus.

The consideration of these facts leads to the observation that the sanatorium has the advantage of other institutions in the possibility of developing within its walls an atmosphere which is wholesome and uplifting. This atmosphere or spirit of the place is a very important and powerful factor in the restoration of the neurasthenic invalid.

The sanatorium, if it is not too large and institution-like, lends itself most readily to the maintenance of such a household tone as well as to the development of all the activities which enter into the daily life of the patient. For instance, the question of work and occupation requires the fullest expansion. No sanatorium can afford to be without an arts and crafts department,

[3] Theodore Diller: Jour. Am. Med. Asso., vol. liv, no. 24, 1910.

[4] "The Need for a State Institution where the Suspected Insane may be Temporarily Detained for Observation Pending Final Commitment."

but so far in this country the outdoor occupations have not proved as effective as they should. The benefit from games and all kinds of diversion is very great, and this branch of activity should be more thoroughly studied. All these things and many others can only be most perfectly developed under conditions such as exist in a suitably located and properly conducted sanatorium.

There is no further need of mentioning other advantages which belong especially and peculiarly to the sanatorium. Alas, too, there are numerous evils and deficiencies in actual sanatorium practice as exemplified in this country. Many of our establishments are poorly equipped and badly managed, and, worst of all, the chief aim and purpose of some institutions is quite purely commercial. Whatever the defects that prejudice many physicians against our sanatoria, this much cannot be gainsaid, namely, that the sanatorium principle or idea is fundamentally correct, and when properly carried out it is superior to all other methods in the treatment of neurasthenia and the psychoneuroses.

If the fact is accepted that sanatorium treatment is the best for cases of neurasthenia and the psychoneuroses, the question is pertinent whether there are enough special institutions or other satisfactory accommodations for all the patients requiring such treatment. The answer is emphatically, "No!" The wealthy can visit the better grade, high-cost sanatoria or otherwise compel conditions to be made right for their cure, but the middle and poorer classes, if they go away from home, can do little else than frequent a more or less indifferent boarding-house or become a ward patient in the general hospital. These unfavorable conditions and the lack of suitable treatment combine to make the recovery of the patient slow and unsatisfactory. In brief, there is no proper institution, no suitable place, to send the impecunious neurasthenic or any psychoneurotic patient without means.

Now the three questions which I want to propound to you are these: First, Is the number of this class of patients great enough to warrant the establishment of a sanatorium for their benefit? Second, Should such an institution be established by private philanthropy, or is it a legitimate object to which the state should contribute its funds as it does to its other charitable institutions? Third, What kinds or classes of patients should be admitted for treatment?

The answers to the first and third questions can be readily made. As regards the first question, the testimony of physicians everywhere indicates that under the pressure of present-day civilisation the number of neurasthenics as well as the number of all other kinds of nervous affections is increasing. Practitioners in the country towns may not fully realize this fact. Nevertheless I venture to say that every one of these members of our profession has in his practice one or more such patients who would be greatly benefited if they could be sent away from the home environment and given the advantage of proper sanatorium treatment.

The answer to the third question can be given without much hesitation. First and foremost, the psychoneuroses should be admitted; that is to say, cases suffering from neurasthenia, psychasthenia, hysteria and hypochondria, the latter not of the severe type. Next, many of the functional neuroses could be received, such as neuritis, migraine, chorea (if not too marked), vasomotor disturbances, etc.

Cases afflicted with melancholia or any evident mental disorder, epileptic patients or alcohol and drug habitués should not be admitted. The main criterion for admission should be to avoid receiving any case which will have a too marked depressing or disturbing effect upon the general household.

Another function of the colony-sanatorium would be to serve the purpose of a psychopathic institution. It might not do this to the fullest extent, but it undoubtedly would in very great measure. A certain proportion of border-line cases, however, would be too eccentric, or otherwise exhibit behavior too suggestive of an impending psychosis, and such patients would be unfairly disturbing to the general household.

Right at this point it may be permitted for me to state very briefly my views on the establishment of a psychopathic hospital and the disposition of the class of border-line cases just referred to. The group of patients who should be subjected to more or less detention, care and treatment on account of doubtful sanity can best be managed, in many opinion, through the medium of psychopathic wards in the general hospital. A separate institution either entirely alone or as a branch department of an insane hospital would soon be subject to the usual stigma attached to the abode of mental patients. As regards the question of mental integrity, the public seems to think that once to be suspected is almost as bad as to be actually insane. Hence, to be an inmate of a general hospital would afford ample protection from unfair criticism and suspicion, and the psychic problem would be solved under the happiest auspices.

The answer to the second question, whether the state or private philanthropy should found and conduct a colony sanatorium for the treatment of functional nervous diseases, is not as readily given. Every nervous specialist, however, and most general practitioners who have had much to do with nervous patients (if they carefully consider the question), will be inclined to answer that the state ought to build and operate such an establishment. There can be no reasonable doubt that this is a fair, wise and economic proposition, one eminently worthy of the serious consideration of the commonwealth.

Briefly stated, some of the reasons for the establishment of such an institution are these:

First, The number of patients needing treatment is great; hence there is demand.

Second, There are no suitable institutions or places of treatment for these patients.

Third, Such an institution would prevent more serious illnesses:

(1) Many cases of ordinary nervousness, impending neurasthenia, hysteria, etc., would undoubtedly be aborted by suitable treatment and removal from the aggravating home environment.

(2) It is certain also that some cases of impending psychosis would be checked.

To accomplish such results as these would alone justify the founding of the institution.

Fourth, Such an institution would effect more rapid cures than could be obtained under any other kind or form of treatment.

Fifth, A certain proportion, and a not inconsiderable one, of chronic cases hopelessly drifting along as burdens to themselves and families could be cured by proper sanatorium treatment. The saving of such patients from the fate of becoming physician and dispensary "rounders" or surrendering themselves abjectly to chronic invalid habits would have a very positive economic value, to say nothing of the great relief of both individual and family suffering.

Sixth, The more rapid relief and cure in acute cases would lessen the period of disability. This would mean an economic saving, both direct and indirect, in very many families throughout the state. The value of the earlier return to work, either as the wage-earner or, as the woman, head of the family and home, cannot be estimated, but it certainly must be great.

If the above statements are true, is it fair or right for the state to wait for private charity to do the work which has so decidedly an economic as well as humanitarian significance?

A brief glance at the history and experience of other nations in the foundation of sanatoria for the poor will show what their answer to this proposition has been.

Benda was the first to introduce the idea in Germany, but his pamphlet on "Public Institutions for Nervous Patients" made little stir. In 1891 Krafft-Ebing aided the movement by a public report urging the establishment of these special sanatoria either by private charity or by the government. But it was due largely to the writings of Moebius in 1894 and 1896, followed by the hearty endorsement and urgent pleas of the greatest authorities in neurology and psychiatry, such as Erb, Forel, Kraepelin, Strümpell, Jolly and Laehr, that finally an establishment was built and in 1899 set in operation. This institution, called Haus Schönow, near Berlin, can receive about 75 patients. It also has an out-patient department. The cases received are all from the working class, and the weekly charge averages about $5. In 1902 the second institution was founded near Göttingen, this one being built by the government. Since then colony-sanatoria have been established in Sachsen Weimar, in Hesse, in the Rhine province, and recently the city of Frankfort-on-the-Main has set aside $100,000 for this purpose. Some years ago Switzerland established the "Colonie-Friedau." Sweden is now preparing to found an institution modeled after "Haus Schönow." At the Second International Congress for Assistance to the Insane, held in Milan in 1906, this resolution was adopted: "The Congress expresses the desire to see organized popular sanatoria for the nervous, erected in suitable locations, open to all without preliminary formalities, as is now being done in Germany."[5]

The first institution for the nervous poor in this country was founded in Boston in 1873 under the will of Seth Adams, himself a neurasthenic. This admirable institution, the "Adams Nervine," accommodates under 50 patients, many of whom are treated without charge.[6] Within the past year a very progressive step has been taken by three neurologists in New York. As the result of the earnest efforts of Drs. Joseph Collins, Pearce Bailey and Joseph Fränkel a neurological institute has been established for the benefit of the wage-earning middle and lower classes.[7]

The fact that, both here and abroad, every institution and every other provision for the nervous poor is strained to the utmost to meet an increasing demand for accommodation and treatment would seem to be irrefutable evidence of the need of sanatoria such as proposed. However, it may be questioned whether the state should assume another charitable enterprise of this character, and in order to settle this matter fairly I would recommend that Connecticut follow the lead of Massachusetts and that our society urge upon the General Assembly the appointment of a committee to ascertain the wisdom and advisability of establishing such a colony-sanatorium for the nervous poor.

The following resolution has been passed and approved by the Legislature of Massachusetts, and the committee has been appointed and is now at work. It reads as follows:

"*Resolved*, that the governor, with the advice and consent of the Council, shall appoint a commission of five persons to determine whether it is expedient and practicable to establish and maintain a state hospital or sanatorium for the cure of cases of nervous breakdown and for patients who are suffering from nervous or mental disturbance not amounting to insanity. If the commission shall determine in favor of such a hospital, it shall present to the General Court a bill or bills embodying the legislation which it wishes to recommend. The commission shall report to the General Court not later than the first day of January in the year nineteen hundred and eleven. The commissioners shall serve without compensation, but may expend for their incidental and contingent expenses a sum not exceeding five hundred dollars."

Gentlemen of the Connecticut State Medical Society: Some time ago there was placed in the hands of a few of your members a banner on which was emblazoned "A State Colony for Epileptics." For nine years these members held that banner aloft and repeatedly stormed the State Capitol. At last, on the outer ramparts of that building,

[5] G. W. Jacoby: "A Colony Sanatorium for the Nervous and Neurasthenic; a Much-Needed Philanthropy." New York Med. Jour. April 15, 1905.
[6] H. R. Stedman: Jour. Nerv. and Ment. Dis., August, 1905.
[7] Collins and Bailey: Jour. Am. Med. Asso., vol. lv, no. 5, 1910.

this standard was securely planted; to-day the State Colony for Epiletics is one of the assured and worthy charities of this good old Commonwealth. Gentlemen, the Connecticut Medical Society has had a hand in many worthy projects. It has sought not alone to raise its own standard of efficiency, but it has also fought for the well-being and physical improvement of the citizens of the whole state. Such an organisation as this cannot stand still; it must always fight and lead the way to better things. Therefore, unless some one can name a better cause, I place in your hands to-day another banner which some of you must carry unflinchingly to the front until it too shall grace the outer ramparts of our State Capitol. The words on this standard which I now hand you are, "A State Colony-Sanatorium for the Nervous Poor."

## ALIMENTARY GASTRIC HYPERSECRETION AND GASTRIC ATONY.

BY A. E. AUSTIN, M.D., BOSTON,

*Director of the Clinical Chemistry Laboratory, Mount Sinai Hospital.*

One criticism applicable to almost all the German works on gastric diseases is the very meager attention given to functional disturbances of digestion, or the so-called nervous dyspepsia, which all will agree is only a part of a general neurosis, but one to which the patient ascribes the greater part of his discomfort and one which must be treated per se, while hygienic measures may be employed at the same time for the restoration of the individual to a normal condition of nerve stability, be it by hydro-electro- or psychotherapeutic measures, for it is not sufficient to say simply that the patient is suffering from nervous dyspepsia, and that he may eat, as Abernathy once said, "The shovel or tongs," implying, of course, that such an individual may eat anything with impunity. Simple as it may seem in many cases, the greatest effort of the practitioner is to induce the patient to eat at all, for one article of food after another is rejected by the patient as disagreeing, until one wonders what has saved him from the fate of Tanner or Cetti. In 1907, however, there appeared from the pen of Zweig, in Vienna, a short work on the treatment of gastro-intestinal diseases, in which due attention has been given to the differentiation and treatment of the various forms of so-called nervous dyspepsia, and though all are functional and, as one author contemptuously remarks, may be dissipated by a week at the mountains or seashore, as if this made them unworthy of study, Zweig has made them one of the most interesting chapters of his book, and particularly adapted to the uses of the American physicians, since, from experience in the German gastro-intestinal clinics, I cannot say that nervous dyspepsia is by any means lacking, though the cases of that form of functional gastric disease are vastly in the minority as compared with the true gastritides and old unhealed ulcers. Among the forms of functional gastric disturbance two varieties are emphasized in this book which are commonly confounded in clinical laboratories from their common quality, largely increased amount of gastric contents withdrawn after a test breakfast, and these two types form the title of my article. While great variations occur, it is probable that 100 ccm. represents the average normal amount withdrawn from the healthy stomach one hour after the test breakfast without the aid of water, and 150 ccm. if the stomach be afterward washed out and its contents estimated by the method of Mathieu-Rémond. Formerly, 60 ccm. was regarded by me as the average amount, probably from the results derived from the expression method, but with the aid of the suction produced by a good bulb, the amount averages much larger, while the washing and calculation gives the largest amount of all, but, on account of its inconvenience, demanding the double estimation of the gastric acids, is rarely used. Now, when the amount withdrawn after a test meal increases to 200 ccm. when simply withdrawn, or to 350 ccm. to 500 ccm. when the stomach is washed, we originally ascribed it at once to atony, particularly if succussion could be found in the patient at the same time. We owe it to Elsner and Zweig to have shown that splashing may occur in a stomach with not more than 50 ccm. in it in which there is not the slightest evidence of any motor disturbance. Hence we are forced to find some other cause for our increased gastric contents after a test breakfast, and this has been done by Zweig and Calvo in the detection of a typical digestive hypersecretion, which is not at all synonymous with the intermittent or continuous variety; fasting, the stomach is always empty, and food of any sort, but more particularly imperfectly cooked foods, as well as alcohol, cause an exaggerated action of the gastric glands and thus produce a largely increased amount of gastric juice. It is quite important that a definite diagnosis be made between these two conditions, for while the causation is much the same, worry, long and intense application to business, particularly when the latter is not prospering, as well as hard study before and during examinations in students who pay little or no attention to the demands of hunger, the latter conditions apply much more closely to hypersecretion than to hypotony, as some call it, for the latter is much oftener associated with a general myasthenia, increased or exaggerated, with reference to the stomach by the local conditions. Musser has reported some instances of this condition in students, but whether associated with hypersecretion, he dose not state. The treatment, however, differs decidedly, and hence the importance of distinguishing these two conditions. In alimentary hypersecretion, on account of the irritation produced by food, the meals should be limited to three daily, and effort should be made, by the use of belladonna preparations, to limit the amount of secretion or, even better, by the use of methylatropine nitrate (Eumydrin), in tablet form or with milk sugar, in doses of from (0.001 to 0.0025 gm.) 1-60th to 1-24th gr. before

meals; in case of atony, however, the meals should be more numerous, at least five, on account of the lack of motility of the stomach to empty itself, and resource should be had to nux vomica tincture and the strychnia preparations. Now as to the method of distinguishing between these two conditions, which demands nothing more than a good centrifuge with graduated tubes. I have made use of those which are carefully graduated in tenths of a cubic centimeter to 10 ccm. and then have a mark at 15 ccm. One or, better, two of these are filled to the 15 ccm. mark with the contents, and then centrifuged for three minutes at about 3,000 revolutions per minute; if the solid contents only fill the tubes to 3 to 5 ccm., 20 to 33⅓%, and an average of both tubes should always be taken, we have a case of hypersecretion before us; if, on the contrary, the solids fill the tubes to 7½ to 10 ccm., 50 to 66⅔%, we are dealing with an atony of the stomach. This also makes an excellent preliminary preparation for further analysis, since the fluid portion is freed from all solid particles and can be used for the determination of the acids, ferments, etc. Perhaps a few illustrative cases will make these points more evident.

CASE I. C. A. W. Nausea and vomiting, particularly mornings, mild insomnia, moderate gastroptosis (to umbilicus). Gastric contents, one hour after test breakfast in four examinations, extending over a period of four months, amounted respectively to 155 ccm. with 33⅓% solids; 131 ccm. with 33⅓% solids; 143 ccm. with 25% solids; 73 ccm. with 33⅓% solids and 87 ccm. with 33⅓% solids. The hydrochloric acid varied from 26 to 30, and examination of the feces of the same individual showed numerous fatty acid crystals and soaps, as well as meat fibers, small mucin fragments intimately mixed with the feces and studded with shrivelled epithelial cells. Although this may be almost on the border line, it was regarded as an alimentary hypersecretion and steadily improved under faradism and stomach washings of first tannic acid and then alum, with restricted diet.

CASE II. Patient of Dr. J. S. Chase. The amount of the gastric contents was 350 ccm., in which the solids were 3%. Hydrochloric acid was equal to 9. Only one opportunity was afforded for examination of this individual, but it undoubtedly belongs to the group of alimentary hypersecretion.

CASE III. R. H. Distention and pressure after eating, no insomnia, occasional vomiting, fasting stomach empty, succussion sounds, no gastroptosis. The stomach contents after test breakfast amounted to 122 ccm., of which 16⅔% is solid. Hydrochloric acid is 48. This is another case of hypersecretion and not of lacking motility.

CASE IV. G. B. Headaches, nausea, occasional vomiting, fasting stomach empty; gastroptosis with gastrodiaphan in stomach, lower border 2 inches below umbilicus; smaller curvature 2 inches above same. The amount of stomach contents on two examinations at intervals of thirty days was 150 ccm. and 155 ccm., with solids 25%, free hydrochloric acid 52 and 57; twenty-four hours urine, 1,330 ccm. This is again a case of alimentary hypersecretion.

CASE V. J. J. M. Vertigo, headache and vomiting, some insomnia, succussion sounds and lower border of stomach at the umbilicus. The gastric contents after a test breakfast amounted to 180 ccm. with 50% solids; free hydrochloric acid, 66; twelve hours after a Riegel test meal, 120 ccm.; total twenty-four hours urine, 564 ccm. In this case the large amount of solids, 50%, points distinctly to lack of gastric motility, which also is confirmed by the small secretion of urine.

Regarding 30 to 40 as the normal for free hydrochloric acid, as given by Zweig, our attention is called at once to the fact that hypersecretion may exist without an excess of this acid; in fact, in two instances, the amount is less than normal, while in another it is not far from normal, 48. In one case only (IV) does the amount approach in any way that found in hyperchlorhydria; in the hypomotility, however, the amount is increased to 66, which is probably due to irritation produced by the delay of food in the stomach. That this increased amount of gastric contents in the former group is due to a true hypersecretion and not to a transudation from the water of the blood, or to a delayed absorption, is proven by the fact that the hydrochloric acid keeps so near the normal point and does not undergo dilution. Hypotony, according to Zweig, is not always accompanied by increased hydrochloric acid, so that this factor would be of little aid in distinguishing between these two forms of gastric neurosis. A marked difference can be noted in the amount of urine in hypersecretion and hypotony; the former apparently does not diminish the urine markedly, while the other does; in fact, so common is the distinction that it can be used as confirmatory of the results obtained by the centrifuge test.

As far as symptoms go, we can detect no apparent difference; both are accompanied by the usual stigmata of gastric neurosis, fullness and pressure after eating, and even before there can be the slightest possibility that the stomach is filled with food, anorexia, nausea and occasional vomiting. The question of vomiting should be inquired into carefully; with the usual exaggeration of neurasthenics, any regurgitation of the food into the mouth is called vomiting, and two patients of mine insisted that they vomited everything they ate, and apparently thought they told the truth, but their blooming appearance and lack of emaciation negatived any such statement, and after lively questioning the statement was modified and limited to a portion of everything eaten, which finally resolved itself into regurgitation of a few mouthfuls of every meal. The presence of splashing sounds proves no means of differentiation between these two conditions, as was noted in III and V, two entirely different conditions, as the precipitation test showed; in fact, Oser, in his clinical instruction, used to emphasize the fact that succussion sounds were of no value except to indicate the position of the stomach; if these sounds were heard at or below the umbilicus, it indicated that a portion of the stomach and, necessarily, its contents were under the fingers, but did not inform you whether you were dealing with a gastroptosis or a gastric hypotony; this, as stated above, has also been verified by Elsner and Zweig in producing succussion in a normal

stomach; it is much more likely to be found in air eaters, or sufferers from aerophagy, if one wishes a technical term. It can be plainly seen that there is a marked difference between the so-called hypersecretion and the hyperchlorhydria; the former is only the secretion of an abnormally large amount of normal gastric juice, while the latter is apparently the stimulation solely of the hydrochloric-acid-producing glands by which we may have a normal or slightly increased amount of gastric juice, but an increased relative quantity of the mineral acid. Just what regulates this percentage of acid is not fully demonstrated. Bickel, from experiments on animals and on humans, on whom both gastrostomy and esophagotomy have been performed for disease, so that pure gastric juice can be obtained, has found that the percentage of hydrochloric acid remains very constant when the flow is excited by psychic influence, as the sight or odor of food, or by allowing the mastication of food which passes out the esophageal fistula; this percentage remains in humans at 0.42%, an amount much higher than is found clinically; this in ordinary nomenclature would equal 115 and it is exceptional to find in severe hyperchlorhydria the free acid beyond 90 to 100. Of course the protein in the test breakfast or test meal by combination largely reduces this, and it is still further reduced by mucin and the so-called "dilution secretion" of the pyloric portion of the stomach; whether this acts in a compensatory way to ameliorate the effects of increased acidity is not known. An occult hyperchlorhydria, however, is recognised where the flow of juice is very rapid after food is taken, with increased procentual hydrochloric acid, but at the usual interval of one hour after the test breakfast this "dilution secretion," which is slightly alkaline, has so increased that the contents as a whole presents the usual acidity; naturally the total gastric juice must be markedly increased, with perfect motility of the stomach, so that what we here regard as alimentary hypersecretion may be a masked or occult hyperchlorhydria; of course a withdrawal and examination of the gastric contents before the hour interval would show this, but I do not know that sufficient examinations of this sort have been made to establish this principle. Bickel's explanation of hyperchlorhydria is that the gastric juice as a whole, with its constancy in mineral acid (0.42%), is increased in amount without change in its composition, but that the motility of the stomach is greater where the percentage of hyperchlorhydria is found increased and the neutralizing elements and water are forced out, leaving the hydrochloric acid in greater proportion behind. It seems difficult to imagine this selective influence by which the pylorus allows the watery elements to escape without the acid, but it is no more astounding than the separation of the proteases from the native proteins, though the latter be in the liquid state. According to Cannon's investigation, however, some of the hydrochloric acid must escape through the pylorus because this portal does not open until free hydrochloric is established. It is often difficult to reconcile scientific medicine with clinical experience, but if we bear in mind that only in the pyloric portion of the stomach does true admixture of food elements and gastric juice take place, while in the fundus, where the major portion of the food remains, only on the portions or layers of the food contiguous to the gastric mucous membrane does it, the food, come in contact with the gastric juice, and a homogeneous mixture is only found when the gastric contents are withdrawn with the tube, we may explain these differences. In fact, if we would regard increased or diminished motility as confined to the pars pylorica and not to the stomach as a whole, as it is usually regarded, we could perhaps explain these inconsistencies; with increased localised motility, the increased and slightly alkaline "dilution secretion" leaves the stomach, leaving the more concentrated (in hydrochloric acid) gastric juice behind; this mixed with foods is the portion withdrawn by the tube. In Bickel's experiments no portion of the gastric juice passes into the intestine, but comes through the fistula as secreted, a composite whole. Hence, his "dilution secretion," instead of passing into the intestine before it is thoroughly mixed with the true gastric juice, becomes an integral part of it and holds its acidity at a normal standard. Note that, curiously enough, this view changes our entire clinical notions in regard to motility. An increased procentual hydrochloric acid which has been regarded as associated with lack of motility, due to the stimulation of the peptic glands by the delay of the food in the stomach, becomes, according to Bickel, a much greater flow of gastric juice produced by the delay of food, but this is accompanied by increased motility by which the watery portions are eliminated. May not eventually the so-called impaired motility turn out to be due to lacking nervous impulse to the fundus dependent on delayed chemical digestion or liquefaction of the contained food? Strauss, working with the means afforded by physical chemistry, viz., freezing point and specific gravity, has attempted to show that the "dilution secretion" strives constantly to render the gastric contents isotonic with the blood and not necessarily to regulate the concentration of the HCl; in this respect he is much more in accord with the views of Bickel, who would make a simple hypersecretion of normal gastric juice, beyond the needs of the food for isotonicity, the abnormal form which is variously known as hyperchlorhydria and hypersecretion without differentiation into true gastric juice and dilution secretion; in fact, Bickel could know little of the latter, if dependent on food, for in his experiments no food entered the stomach to excite it. There seems to be ample ground for the contention of Strauss, since in hypersecretion there is a lowering of the freezing point and specific gravity of the gastric contents even when the test breakfast has been given after the stomach is thoroughly washed out. Fat causes no flow of gastric juice as explained by the Pawlow school, because the latter, outside of the very tiny

amount of steapsin which it contains, has no digestive influence on fat; furthermore, added to protein food in the form of butter, neither in the normal individual nor in the sufferer from hypersecretion does the mixture call forth as great a flow of gastric juice as the same amount of protein food alone; we can hardly speak of an insoluble substance as affecting the freezing point of gastric contents, but on account of its lesser weight than water it certainly affects the specific gravity of gastric contents by requiring less of the gastric juice to grant to those contents the same commensurate weight as that of the blood; hence fat which has proved very effective in the treatment of both hypersecretion and hyperchlorhydria may act by its physical properties rather than by its influence or lack of influence on the reflex stimulation of gastric juice. Just why this increased secretion of gastric juice should be associated with any symptoms at all is doubtful; it is usually the concomitant of a neurosis in which apparently all functions, muscular, sensory and secretory, are exaggerated. The digestion in a normal individual is carried on with a slight increase in metabolism and a rise of temperature, and in individuals in whom the process is exaggerated, demonstrable to us at present only by increased gastric juice, but possibly in the future by other evidence, we may well expect signs of fatigue like headache, insomnia or the unrefreshing sleep of those who awake "as weary as when they went to sleep." Hence, if we can only check one of these exaggerated functions, secretion, be it of the stomach or the kidney, for the "urina nervosa" is also well recognized, we shall, to some extent at least, stop the leak of nervous energy. Bed, while efficacious in impaired gastric motility, especially in those impaired in weight by avoidance of food or those with thin abdominal walls and general ptoses, does not seem to agree with those sufferers from hypersecretion; milk, whether on account of its fat or liquid character, acts admirably, and, as there is usually no question of impaired motility, can be given in large quantities. On account of the excessive susceptibility of the gastric glands to normal stimulus, three meals only per day are more desirable. The medicinal treatment, as has been mentioned, consists of the employment of belladonna, atropine, or, better, its methyl nitrate to neutralize the over-susceptibility of the secretory mechanism.

## THE FUNCTIONAL SPINE.*

BY JOHN D. ADAMS, M.D., BOSTON.

THE diagnosis of osteo-arthritis is made in a number of the back cases we see in clinical work. The presence of one or two of the classical symptoms of that disease will not allow many to jeopardize the advantages of early treatment, but results show many times that the symptoms present do not justify the diagnosis of osteo-arthritis. Should we make a diagnosis of osteo-arthritis without the verification of x-ray findings? With the high standard of x-ray work existent, is it not possible to recognize and interpret pathological conditions in bone sufficient to produce the localized symptoms — pain, muscular spasm and limitation of motion? Whether the condition present be of muscular, nervous or bony origin, the classical treatment of supporting the back with jacket or brace is acceptable to all of these conditions, but is it always justifiable?

All the cases we see in clinic work are from the laboring class and illustrate the predisposing factors of either exposure inconsistent to the power of resistance or occupation demanding the constant use of the back, which in time becomes excessive to its capability, or, more probably, a combination of both.

The function the back performs in the pursuance of work among the laboring classes is an important one, and being incapacitated in any way is of vital importance. Pain and discomfort in these cases are not always true indicators of the condition present, as the degree of tolerance varies with each individual.

The average person of the laboring class is, on the whole, rather tolerant of a moderate amount of pain. He resorts to proprietary medicines and plasters, from which he may receive some temporary relief, before he finally presents himself at the clinic, either wholly or partially incapacitated for work.

Subjectively, the patient places his hand over the region of the lower dorsal and upper lumbar spine as indicating the area of pain. He describes it as being in the nature of an ache and a stiffness on attempting to straighten up from a stooping posture. He notices it most on getting up in the morning, it taking him some time to get limbered up, as he expresses it.

Examination shows voluntary limitation of motion in the spine as evidenced by flexion in all directions being stopped by muscular spasm. Especially is this noticeable on forward and lateral bending, but hyperextension, where the spinal muscles are relaxed, is not limited. Now, by forcing the patient to full lateral and forward bending, disregarding the pain, and, to a certain extent, overcoming the spasm, it will be noticed that the spine itself is capable of practically full motion in all directions. In other words, we have a functional back, pure and simple, to deal with. Now assuming that the x-ray is negative, what are we justified in doing in the way of treatment for this patient? It is safe to say that early in his affection he has resorted to the proverbial plaster and may possibly have gotten some temporary relief. He has also tried all of the patent liniments on the market and had his quota of antirheumatics, and, finally, in sheer desperation, seeks out the hospital clinic.

Many of these men are teamsters riding on swinging or spring seats. Some are longshoremen, engineers, tailors, etc., but suffice to say that in all the character of their work necessitates the constant use of their back muscles. This strain is often enhanced by inclement con-

* Read before the Mt. Sinai Hospital Clinical Society, Oct. 13, 1910.

ditions, such as sudden change of temperature or exposure to heat and cold.

The natural internal resistance in the normal healthy individual will often conceal any ordinary abuse to a given part of our anatomy, but finally nature rebels, and that is the condition of affairs we have in this class of cases.

The one principle in the treatment of this class of cases is obviously that of rest. This should be accompanied, if possible, by a method which does not incapacitate the patient for work. Naturally the simplest course would be absolute rest in bed, but that is out of the question, for there is a family to support in the majority of cases, and the danger of losing work. Invariably the suggestion of strapping the back is treated with contempt accompanied by the expression, "Oh, I have had that done, and although it felt better for a time, the pain returned as bad as ever." The next procedure is usually that of a plaster jacket. Now a plaster jacket, intelligently applied, with all the necessary requirements for efficiency, is at best a cumbersome, uncomfortable thing to wear, and although we may gain our principle of support, and to a certain extent relief of symptoms, there are certain untoward effects which bring it within the pale of criticism. It is unnecessary to state that the atrophy of disuse is a factor to be avoided, and it certainly does take place in immobilization. Also, the spine is splinted in an area the use of which is very necessary for the satisfactory performance of the patient's work, certainly within the limits of comfort and efficiency.

At the end of such treatment we are confronted with the problem of a chronically weak back, ill supported by the weak muscles, and a constant source of complaint. It has been the writer's experience that there is a growing resentment among such patients to the encumbrances of any such apparatus. This is all based, mind you, on the assumption of the absence of any bone involvement.

The next alternative is that of a belt, reinforced with light steel, and, should apparatus be needed for muscular support, in this are incorporated all the necessary qualifications devoid of appreciable weight and allowing enough freedom of movement to be consistent with comfort and efficiency. Its advantages over simple strapping are that it encases the body in such a way as to act as a purse string, thereby producing equal pressure and fixing the muscles much more efficiently than when we attach adhesive plaster to two sides of the pelvis, which are both movable.

The second principle of treatment is that of counter-irritation, and the various agencies by which this may be produced are well known to us all. The writer wishes to offer a report of twenty-five cases treated at the Boston Dispensary and in private practice. These cases were all routine, unselected; occupation — teamsters, tailors, day laborers, namely, those men employed in a vocation necessitating constant use of the back. All of them presented the classical symptoms of pain, muscular spasm and limitation of motion in varying degrees of intensity. In all the x-rays were negative. Five of the cases were treated three times a week with fly blisters, five with actual cautery, five with strapping, five with plaster jacket and five with heat. The treatment was continued over a period of two months. All were treated personally by the writer, and clinically the results showed conclusively that those treated by heat improved much more rapidly and efficiently than any of the other groups. In fact, at the end of two months all were put on baking.

The apparatus for baking was constructed as follows: A small wooden box 18 by 20, the top being left open, lined with asbestos to prevent radiation, fitted up with six sixteen-candle-power electric lights. The sides were curved to fit the outline of the back. The box was then placed on an upright on the wall and rendered adjustable to any height by a moveable peg in a series of holes in the upright. The patient was then placed on a stool and the heat applied to the area to be treated. The heat was applied to the bare skin, temperature of 300°, for a period of fifteen minutes.

The result showed a marked hyperemia with excessive perspiration and with relief from pain. There were no burns and no untoward effects. The intervals of application were gradually lengthened in accordance with the diminution of symptoms. In most every case a light pelvic belt was applied as an adjunct to this treatment.

In conclusion, the writer would state that in treatment there is nothing new offered, but results show that there is a certain class of occupation spines which, through vocation, present a functional disability, and if we have no facts to sustain an organic or bony change, we are not justified in splinting the back to the extreme detriment of its future capability. We may have present the classical symptoms of muscular spasm, limitation of motion with affection of either nerve, muscular or bony origin. With a muscular strain the spasm present is more or less of a voluntary nature and may be largely eliminated by tolerance of pain in motion, whereas should the affection be of bony origin, the patient has no control over the muscular spasm. It has been the writer's experience to see far too many cases tied up in rigid apparatus, with its untoward effects, where results have shown that they would have been far better to have supplemented a light support with counter-irritation.

## Clinical Department.

### INSTITUTIONAL FORMS OF MANIC-DEPRESSIVE INSANITY.*

BY IRWIN H. NEFF, M.D.,

*Superintendent Foxborough State Hospital, Foxborough, Mass.*

THOSE who are concerned with the care and treatment of the inebriate can appreciate that inebriety is primarily a nervous weakness and

* Read at the September, 1910, meeting of the New England Psychiatrical Society.

that on this weakness is engrafted a habit which can be held accountable for the syndrome which we call inebriety. The inebriate is, as it were, a sum total of his personality and of the symptoms directly related to alcoholism. In many cases the condition is an exaggeration of the characteristics of the patient.

It should be understood that this weakness antedating the alcoholic symptoms often manifests itself early in the life of the patient and is shown as a peculiarity, idiosyncrasy or eccentricity and is not recognized as a marked departure from the normal standard. These peculiarities may seem to have no particular significance, but it is equally true that if critical analyses of these cases had been made it would have been shown that in some individuals an "insane diathesis" might have existed which could have been held responsible for the periodical or occasional outbreaks of drinking.

It should be generally recognized that inebriety is a condition, or, more properly speaking, a syndrome which necessarily must show a varied etiology; therefore it is not surprising that a certain percentage of these cases prove on examination to be psychopaths which may very properly be placed in well-defined insanity groups. When this is proven we can justly say that inebriety is an expression of inherent defects, which defects may be of a psychopathic or neuropathic character.

We have observed such an analogy in not a few cases and have diagnosed manic-depressive insanity in three of our patients. The psychosis has been suggested approximately in fourteen individuals, but, owing to incomplete history and the impossibility of securing authentic after history, ten cases are eliminated from this series. It seems worthy of note that all the cases of this group were sent to the hospital as frank cases of inebriety; apparently the pathological mental symptoms were unrecognized or disregarded by the examining physician.

It is not believed that our experience is unique or that it differs in any degree from the experience of other institutions, as well-defined mental diseases are not infrequently seen in institutions other than those caring for the insane. The classical types of insanity are not uncommonly found in prisons, almshouses, charitable institutions, sanitaria, etc. Often the insanity is not detected until late in the history of the case, although the alienation may have been intimately related to the crime, misdemeanor, defect or disease.

Further comment is reserved to follow the abstracts of the three cases of manic-depressive insanity associated with inebriety.

CASE No. 1.

| | |
|---|---|
| Case number, | 4229. |
| Residence, | Westboro. |
| Birthplace, | Salmon Falls. |
| Age, | 60. |
| Occupation, | Shoe cutter. |
| Civil condition, | Married. |

*Physician's certificate.*—"Reported by others that he would get whiskey and shut himself up in a room until he drank the whole of it, getting intoxicated, abusive and using obscene and violent language.

"Observed by me that he was very nervous and excitable; said that he would give anything for a drink; did not seem as if he could get along without it."

*History as given by others.* — From commitment paper: "Was at a Massachusetts insane hospital for six months as a voluntary patient for nervous treatment; he was called a hypochondriac there; he left the last part of July, 1907. His mother died insane and he had a half-uncle (his mother's half-brother) who was insane; was an occasional drinker up to four years ago; constant at present. Cause of intemperance: 'Supposed to have begun in order to assist a nervous condition of the stomach.'"

*From family statement.* — "No intemperance known in relatives; mother died of pneumonia; cause of father's death unknown; one brother died when a boy. Patient has nervous dyspepsia; says he was told a little whiskey would help the stomach, and so contracted the habit; prefers solitary indulgence; has used asafetida tablets; has talked much of suicide."

Secretary of Overseers of the Poor states as follows: "That he has not been a hard drinker until within the last year or two; has never worked to speak of; sister helps him; thinks he has drunk more or less always, but more since we became a licensed town."

*Hereditary history.* — Father disappeared when patient was two years of age; mother died of pneumonia at the age of seventy-nine; was quite nervous, worried over trivial matters; two sisters and one brother died; one brother and two sisters are living, in good health. One maternal uncle had several attacks of mental depression and was under treatment in asylums. One younger sister is quite nervous. Patient says that all members of his family are of a nervous disposition.

*Personal history.* — As a baby and child was never strong or rugged; was considered quite "nervous"; although he went to school between the ages of six and fifteen, his schooling was intermittent; since his school days he has worked on a farm, in the shoe business and as an ordinary laborer. At the age of thirty-two was married; has no children. His wife eloped with another man after eighteen years of married life. Has had no severe physical disease, but has had attacks of "nervous dyspepsia" since the age of twenty-four. Has a hernia of some years' duration.

Was under treatment at asylum from December, 1906, to August, 1907; while there he had an attack of depression characterized by emotionality and delusions of unworthiness; he does not believe that he entirely recovered from this. Since his discharge from the asylum he has worked on a farm, in a lumber factory and at ordinary laboring work.

*History of present illness.* — In 1898, after desertion by his wife, his attacks of gastric trouble became more pronounced; on account of extreme nervousness from continually bemoaning his fate, in order to forget himself and modify his nervousness he began to drink and he soon found that he had a craving for drink; at times would take a pint of whiskey during the day; again he would go two weeks without drinking; his drinking bouts have always been irregular and have been impulsive; he says that he drinks in order to drown his sorrows and dissipate his feeling of depression; after he drinks he always becomes exhilirated; during the past six months he has had three attacks of mild delirium of short duration.

*Admission note.* — Is quite nervous, somewhat garrulous and his conversation is circumstantial and spontaneous; is anxious to tell of his experiences and

it is evident that there is introspection of hypochondriasis; has some insight into his condition and says that he is anxious to overcome his craving for drink as he is conscious that it is detrimental to him in every way.

*Inspection and physical examination.* — Man of average height; general muscular development fair; head well shaped; forehead broad and straight; face long; eyes blue; sclera clear; arcus senilis and arteriosclerosis present; abdomen prominent; left inguinal hernia; ears large and well shaped; left shoulder a little higher than right; co-ordination good; pupils react normally to light and distance; teeth, many missing; tongue clean and somewhat tremulous; knee-jerks sluggish. Lungs negative. Heart negative. No change in liver dullness. Inguinal glands normal.

*Before staff, Dec. 19, 1908.* — He does not believe that his condition is different than one month ago; has noted that there have been times since admission when he has been depressed and at other times felt more happy and contented. Depression following retrospection. Says, upon being asked, that he has been a good man excepting for drink. Went to the asylum on his own volition to get over nervousness; has been troubled with nervousness for sixteen or eighteen years, long before he began drinking. Began to notice that small things upset him and at such times could not work as he was too nervous, these periods of nervousness coming on at intervals from two to three weeks; ten years ago stopped work on this account; has found it hard to begin any work, but when started he wanted to rush through it; never is real happy and has not been since family troubles begun. Wants to sit by himself when depressed periods come on and tries to throw them off; when in this condition sleeps poorly; believes he will never be better. Longest attack was of three or four months' duration, sixteen years ago, and has had many attacks of two and three weeks' duration since; thinks drinking has made him more nervous and admits that he has had ideas of self-destruction, but has been able to control them.

Diagnosis: Manic-depressive insanity, eighteen years' duration.

It is believed and acknowledged by him that his insobriety was the result of nervousness, patient resorting to stimulants to modify despondency or abort depressive attack.

*Recapitulation.* — Man, age sixty; family history of insanity; manic-depressive syndrome developing at age of forty-two, preceding the alcoholic symptoms, inebriety developing at age of fifty coincident with "nervous dyspepsia" (gastric symptoms of mental depression); patient resorts to stimulation to modify or abort mental depression. Previous treatment at a Massachusetts hospital for the insane. Diagnosis: "Hypochondria." Patient eventually secures admission to an asylum as a voluntary case.

## Case No. 2.

| | |
|---|---|
| J. D. L. | |
| Case number, | 4641. |
| Residence, | Boston. |
| Birthplace, | Connecticut. |
| Age, | 52. |
| Occupation, | Caretaker. |
| Civil condition, | Widower. |
| Commitment, | Voluntary. |

Abstract of former history:

Admitted Nov. 14, 1903. Discharged Nov. 29, 1904.

At time of admission it was stated that he had been a periodical drinker for twenty-three years. It was also reported that he showed the effects of inebriety of many years' duration.

Physical examination at time of admission was of negative value.

Experienced the usual effects of excessive drinking, but rapidly recuperated.

March 6, 1904, was allowed to go on a visit; March 9 was returned by an attendant in intoxicated condition.

*Hereditary history.* — Father is living at age of eighty years; is in good health and has always been temperate. Mother died at age of twenty-five years of puerperal fever. Patient is only child by first marriage; father had three children by second marriage; all are in good health; no defect. Grandparents were long lived and healthy. A few maternal relatives were somewhat weak, but defect is not specified. Paternal relatives were robust. No history of inherited disease.

*Personal history.* — As an infant and boy was delicate and developed slowly; was quite nervous until the age of eleven years; had an attack of typhoid fever; convalescence was protracted; after recovery developed rapidly and became considerably stronger. Received but little parental training.

Went to school from ages of six to fifteen years, going through grammar school; afterward worked in a grocery store for thirteen years, then was a meat cutter until six years ago; since that time he has been a janitor, caretaker and farm laborer.

Was married at the age of twenty-three years; wife died two years ago; has three children who are grown up and in good health. Has experienced no accident. Has been arrested twice for drunkenness and placed on probation.

After discharge from this hospital he refrained from drinking for five months; since that time he has drunk periodically. Had Keeley Cure treatment some years ago and during the past two years has been treated by Emmanuel Movement.

*History of present illness.* — At the age of twenty-three years drank occasionally; had a liking for liquor, but worked steadily and was not incapacitated; habit has been confirmed during the past twenty years. While for a time he drank irregularly, he has during the past nine years been a periodical drinker; of late periods have developed every six weeks. Experiences the usual effects of alcoholism with a pronounced feeling of depression. This despondency also exists just before his drinking period, which he describes as a "fit of melancholy." Believes his drinking is the result of an effort to dissipate this feeling. Acknowledges, however, that occasionally he has drunk when this feeling was absent. This feeling of depression is to a great extent dependent upon his environment, work and physical condition. An examination of the patient showed quite clearly the mental stigmata of neurasthenia. Three weeks ago experienced an attack of depression and resorted to alcoholic stimulation.

Four days previous to his admission to the hospital he consulted the superintendent and was advised to return for treatment.

*Inspection and physical examination.* — Height 5 feet 7 inches. Muscular development good. Subcutaneous tissue moderate. Face angular, deeply lined, nose prominent. Skin dry and smooth; some moles on head. Ears of moderate size, set close to head. Upper teeth missing; tongue coated. Palate broad and arched; pupils equal, slight arcus senilis. Glands not generally palpable. Chest well-developed. Station erect. Pupils react to light and distance; knee-jerks present. Romberg's sign negative. Heart negative. Lungs negative. Abdomen: Right inguinal hernia, moderate size. Extremities negative.

*Admission note.* — Patient is at present free from the effects of alcohol; gives a good, clear sequential history; says that he has been examined by many neurologists and has been told that his drinking is an expression of mental disease.

Patient was finally discharged from the hospital, as not to be benefited by further treatment, on May 13. When patient left hospital his condition was one of marked depression, which had existed for some weeks; it was learned shortly afterward that he had been arrested for drinking and committed to a penal institution.

After-history of case would show the same variability in emotional condition. On several occasions has called at the hospital and at the present time has been abstinent for two months. Patient, however, fears a return of depression and feels sure that when it recurrs he will relapse.

*Recapitulation.* — Man age fifty-two; attitude that of a pronounced psychopath; possible history of neuropathy on maternal side; retarded development and nervousness during childhood; inebriety developing as periodical drinking at the age of twenty-three, with a history of precedent depression; drinking occurs simultaneously with attacks of mental depression.

CASE No. 3.

| | |
|---|---|
| J. M. H. | |
| Case number, | 4069. |
| Residence, | Boston. |
| Birthplace, | Boston. |
| Age, | 26. |
| Occupation, | Lawyer. |
| Civil condition, | Single. |

*Physicians' certificate.* — Reported by others that "he has been drinking periodically for years; he has had much done for him and has failed to keep sober." Observed by me that "we have both examined him before; we have known of his drinking habits for some time. He shows evidence of recent drinking, which he admits. He consents to go to Foxborough."

*Hereditary history.* — Mother is a decided neuropath; two sisters show peculiarities; maternal grandmother was peculiar; there is apparently an inherited maternal defect; father was intemperate.

*Personal history.* — Patient was usually healthy during childhood; no physical defect. At pubescence he developed a pronounced ego and was unduly optimistic; these conditions were periodically in evidence, he was unquestionably precocious and early developed rhetorical and oratorical talents. Relatives and friends noted this occasional "accession of spirits," but believed it to be due to drinking tendencies, which began at the age of seventeen. At this age he associated with dissolute companions, drank to excess and was frequently intoxicated. For some days preceding his alcoholic debauches patient would talk extravagantly, show extravagancies in conduct and would continuously seek notoriety; excesses of various kinds would be perpetrated; during these exhibitions he would frequently commit some misdemeanor, calling for assistance from relatives and friends; these irregularities were believed to be due to inebriety and accordingly patient was committed to this hospital.

Examination on admission to this hospital showed no physical defect and there was no evidence of physical disease. Four months after admission to hospital patient came under my direct charge. His expression and attitude indicated inordinate self-satisfaction, which was manifested in conduct and speech. He frankly admitted his many misdemeanors, but claimed justification; he also made plausible excuses for his misconduct. He was able to make an accurate and searching analysis of his case. He admitted fits of despondency succeeded by unusual boyancy, but believed that this emotional exaltation was reactive, did not appreciate that it was pathological, and believed that he should be held responsible at all times for his conduct.

During the time patient was under my observation he was irregularly depressed and elated. During elation was garrulous, circumstantial and proposed and carried into execution many extravagancies of conduct. When patient was depressed he was unwilling to engage in work or diversion, quite reticent, introspective and occasionally talked of self-destruction; these changes were appreciated by patient; there was no true insight; patient was sensitive and suggestible; slight departure from daily routine would produce at times a marked reaction. Several times he left without permission and, owing to his mild aggressiveness, was given final discharge as not to be benefited by further treatment at the hospital.

*Recapitulation.* — Man aged twenty-six; pronounced neuropathy in family; irregularities in conduct and peculiarities during pubescence; excessive drinking since the age of seventeen; irregularly depressed and elated, the alcoholism being coincident with elation; not benefited by hospital treatment; discharged seven months after admission.

*After-history.* — Seen nine months after leaving hospital and it was found that patient had conducted himself well; was engaged in remunerative work and had been abstinent for five months; patient, however, appreciated emotional changes and volunteered the information that during the nine months he had had several mild attacks of depression, but no attack of elation. Seventeen months after discharge family stated that patient has relapsed, has again shown silliness in manner, and given evidences of impaired judgment; it would appear that each succeeding attack of elation is more pronounced.

The diagnoses of these cases is a matter of little difficulty if one bears in mind the character of the two phases of manic-depressive insanity. The depression of manic-depressive insanity requires to be differentiated from the depression seen in dipsomania and that often preceding an attack of periodical drinking. The depression of dipsomania and periodical drinking is characterized more by anxiety, restlessness and an uncontrollable obsession. The general inhibition and introspection seen in cases of manic-depressive insanity is not observed. The elation of manic-depressive insanity also requires to be differentiated from the rapid ideation and disassociation of alcoholism. This often requires an accurate clinical history and a close observation of the individual case.

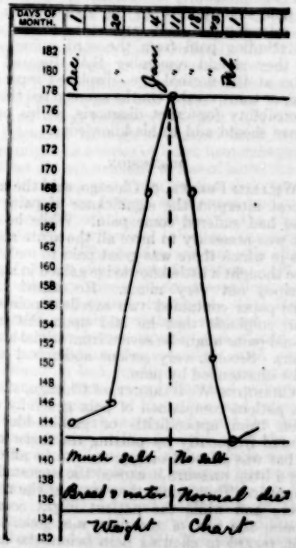
In two of these cases the excessive drinking was coincident with the depressed period; in the remaining case the elation and inebriety occurred simultaneously.

It would, therefore, appear that cases of manic-depressive insanity, mild in type, but with a characteristic and classical syndrome, are often unrecognized. It is obvious that if such a condition were detected in its incipiency improvement might result from treatment, and the degree of responsibility of these cases might be more accurately determined.

Physicians who have observed and studied such cases will recognize that the symptoma-

tology corresponds quite closely to that described as "hypomania" and will bear me out in the statement that it is often extremely difficult to secure the commitment of these cases to a hospital for the insane, as the patient's proper mental status is not understood by the average jury of laymen.

## COMMON SALT AND FLUID RETENTION. A CLINICAL EXAMPLE.



BY EARL D. BOND, M.D.,

*Second Assistant Physician, McLean Hospital, Waverley, Mass.*

THE case following seems to show in an unusually clear way the influence of common salt in building up edema.

The patient was a man of twenty-five; his mental diagnosis, dementia precox of the paranoid type; he was clear, polite, quiet.

About a month after entering this hospital he manifested delusions about his diet. These at first caused him to give up meat, and then, for six months, to take only seven slices of bread and one and a half pints of milk and cream at each meal, with the result that he lost 20 lb. By insisting that he take, in addition to the foregoing, six glasses of eggnog a day, most of his loss in weight was made up during the next month, August. For September and October he returned to his bread and milk diet, and for a short time in November took only bread and water. On Dec. 1 he was taking

twenty thick slices of bread, water, three glasses of milk and some olive oil each day. About Jan. 1 it was noticed that he was sprinkling salt over his bread to take the place of butter. In twenty days his weight increased 32 lb. His legs and genitals were found to be enormously distended with fluid. There were a few moist râles in the bases of the lungs behind. The abdomen was free from fluid. There was absolutely no trace of edema about the eyes; no headache. He was compelled to take a fairly normal diet from which free salt had been excluded. On the first day he lost 10 lb., and in six days 27 lb. During the next seventeen months, to the time of his death from typhoid at another hospital, there was no recurrence of edema.

The question comes up as to what part the kidneys and heart played in producing this condition.

A year before the edema the twenty-four-hour amount of urine was 600 ccm., specific gravity 1.024, and showed the slightest possible trace of albumen and a very few granular casts. At the height of the edema there was a change to 2,285 ccm., specific gravity 1.014, neither albumen nor casts; and as the last of the edema was disappearing the readings were 2,150 ccm., specific gravity 1.013, the slightest possible trace of albumen and no casts. In the absence of subjective symptoms, with no sign of puffiness in the face, and with no tendency to dropsy before or after this one episode, the urinary findings do not seem sufficient to diagnose a nephritis.

Again, a year before the edema the patient's heart showed sounds distinct and free from murmurs, accentuation neither of the aortic or pulmonic second, a dullness well within normal limits. The pulse was irregular in rhythm but regular in force; the artery wall could not be felt. At the height of the edema the cardiac dullness still seemed within normal limits; there was, however, a faint systolic murmur at the apex and an extremely sharp ringing aortic second, with a pulse of high tension. When the edema had gone, the murmur disappeared, the aortic second lost its ringing quality and remained very slightly accentuated. It seems fair to conclude that the heart and arteries were efficient and were not in themselves the cause of dropsy.

The explanation that the unusual amount of salt was the causative factor is perhaps too evident. It is interesting to see what observations have been made along this line. In the laboratory Cohnheim [1] and then Reid [2] demonstrated that sodium chloride passes easily from gut to tissue spaces, but with great difficulty in the opposite direction. Starling [3] explains that this salt, stored in the body, takes up enough water to maintain the normal concentration of the body fluids; that there is almost no diuretic effect and no such efforts to drive off the salt as follow the presence of sugar, for instance, in the blood.

Clinically, Widal and Javal [4] have been able, in nephritic patients, to cause an edema to appear or disappear at will by increasing or decreasing the chlorides. In individuals with apparently normal kidneys, following the ingestion of salt Miller [5] found chloride retention, gain in weight, but no visible edema.

On the therapeutic side, Widal and Javal have shown that the drugs which are considered the best to re-establish diuresis in nephritics, such as theobromine and its derivatives, are precisely

those which have the most powerful action in removing chlorides from the body; that the value of milk as a diet lies in its lack of chlorides, and that solid foods do just as well if the amount of salt in them is kept low.

## Reports of Societies.

### MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

THIRTY-SIXTH ANNUAL MEETING, HELD AT DETROIT, MICH., SEPT. 13, 14 AND 15, 1910.

THE President, DR. FRANK P. NORBURY, Hospital, Ill., in the chair.

After invocation by REV. EDWARD H. PENCE, and addresses of welcome by HON. PHILIP BREITMEYER, mayor of Detroit; by DR. J. H. CARSTENS, president of the Michigan State Medical Society, and by DR. A. D. HOLMES, president of the Wayne County Medical Society, which were responded to on behalf of the association by DR. EDWIN WALKER, Evansville, Ind., the Medical and Surgical Sections convened for the reading and discussion of papers.

#### PAIN IN ABDOMINAL DISEASES.

DR. WILLIAM M. HARSHA, of Chicago, stated that in order to interpret pain properly, a careful history of the case was necessary as pain must be considered in relation to other factors in a given case, and without these it lost its chief importance. The relation of pain to taking food was also of great value, particularly in duodenal or gastric ulcer, or the various stenoses, benign or malignant. The direction and extent of painful radiation and the association with the hyperesthesia, local tenderness and muscular rigidity were of the greatest importance both as indications of the site and gravity of the lesion. The arm pain in angina pectoris, the shoulder or upward radiation in gall-bladder disease, and downward, forward and testicular pain in nephritic colic were well-known examples. The pain of abdominal disease might be either spontaneous or elicited by pressure, body movement or position, and it might be influenced by psychical, thermic, mechanical or chemical means, all of which might be utilized in cases to aid in exact diagnosis. Diseased viscera caused pain at or near their various sites, but there were many exceptions which lent importance to the reflex or referred pains. In most visceral lesions there was a disturbance manifested variously by pain, tenderness, hyperesthesia or muscular rigidity on certain areas of the external or protective portions of the body. As moderate shock or fright would emphasize a vanishing or latent pain, he had tried the faradic current in suitable cases, and in two instances he had been able to locate more definitely the trouble. A great majority of abdominal diseases, especially of the more acute variety, were first heralded by pain rather than by change of size, position or other physical conditions. The surgeon could often gauge the urgency in a given case by the character and severity of pain. Taking cognizance of the value of pain associated with local distentions and peristalsis, or the absence of peristalsis, they might locate a stenosis or other forms of obstruction, calling to their aid submerged palpation, or palpation in the bath, which would enable them to detect induration which was otherwise not palpable. By observing the time relation of pain to other symptoms, the effect of food, drugs, cathartics, cold, fatigue, movement, position, jarring, fist percussion, anesthetics or electric stimulation, they should be able to increase the percentage of correct diagnoses.

The safety of abdominal section might have caused them to relax their efforts at exact diagnosis. It had happened many times that laparotomy had been done for appendicitis when a movable kidney, pyelonephritis, ureteral stone, typhoid fever, diaphragmatic pleurisy, salpingitis or other conditions were present. Age, sex, occupation or previous history might give valuable aid. In childhood intestinal troubles prevailed, and they were likely to encounter appendicitis, intussusception or tuberculosis, and in advanced age malignant disease. In women the pelvic organs were frequent sites of disease, while gallstones were more frequent. Lead colic might simulate organic disease. A history of indigestion, with vague epigastric pain, might aid in determining a perforation of the duodenum or stomach, and a record of previous inflammatory trouble in the abdomen might explain a sudden intestinal obstruction. Among the less frequent conditions might be mentioned the meteorism with abdominal pain resulting from the embarrassed portal circulation in cardiac insufficiency. He had recently seen a case of this kind where the pain was so pronounced and distention so great that abdominal tumor was suspected by one physician. They should consider the possibility of disease of the central nervous system, such as tabes, herpes or hysteria, disease of the spine, as caries, or spondylitis deformans. They should also consider the possibility of disease of the thorax, referring pain and rigidity to the abdomen, or to one kidney, referring the pain from stone to the opposite side. Excluding pain from the cord, spine or reflex causes, they should remember that diseased viscera might be at the normal site, displaced especially by prolapse, or transposed. On the surgeon fell the burden of responsibility for exact diagnosis, as his operative experience should add to his knowledge.

#### DISCUSSION.

DR. WILLIAM FULLER, of Chicago, said the man who could best interpret the significance of pain was the one who had suffered some pain. While he did not think it was necessary to have all the acute abdominal diseases in which there was great pain to make a diagnosis, he thought a little knowledge gained in a practical way helped out very much. He stated that Dr. Harsha's paper contained two excellent points. First was the emphasis that he laid upon the fact that abdominal pains might be severe from trivial abdominal affections. Second, very serious abdominal affections might be unattended by pain.

DR. CHANNING W. BARRETT, of Chicago, stated that when a patient complained of pain generally over the abdomen from appendicitis or gall-bladder trouble they found frequently by putting the finger upon the point that was affected or supposed to be affected and making a little pressure it caused the surrounding pain to disappear. They could then go over the rest of the abdomen, and while the patient might complain of local pain, the rest of the pain was gone. Another point in regard to eliciting pain before the anesthetic was given. An anesthetic was of great value sometimes in pelvic conditions and abdominal conditions, but he thought they gained more knowledge of pelvic and abdominal conditions by examining the patient first without an anesthetic, finding out all they could, and they found then in giving an anesthetic some things

that were apparent before the anesthetic had disappeared.

Dr. L. W. Bremerman, of Chicago, stated in diseases of the kidney or the ureter, he had seen cases in which there was hematuria, with marked pain over the region of the kidney, the kidney being felt on palpation, excessive tenderness over the kidney, a kidney lesion diagnosed, and surgical intervention recommended. Upon cystoscopic examination of the individual, he discovered that the hematuria was developing from the supposedly healthy kidney, the urine from the supposedly diseased kidney being normal. Every method of examination should be resorted to before an absolute diagnosis was made.

Dr. Harsha (closing) stated the thing that most impressed him in studying this subject was the need of considering three or four different sources of abdominal pain. First, the central nervous system; second, the spine; third, the reflexes, and fourth, the visceral diseases themselves.

### THE CAUSE AND SIGNIFICANCE OF TUBAL RUPTURE IN EXTRA-UTERINE PREGNANCY.

Dr. Channing W. Barrett, of Chicago, read a paper on this subject in which he drew the following conclusions: (1) Pregnancy which was considered to be always extra-uterine in the beginning assumed pathologic significance when it underwent ectopic attachment. (2) The ovum attached in the tube had a parasitic action, having a malignant tendency in that it destroyed maternal tissues, embedded itself in the tube wall and tended toward death of the mother, but in "making its bed dug its own grave." (3) The growth of the ovum or enlargement of dead ovum mass, together with the destruction and thinning of the tube wall, led to almost certain rupture of the tube. (4) The primary rupture might be partial and even slight, or it might be complete and even fatal. (5) If complete, a subsequent rupture or subsequent ruptures were the rule. (6) With rupture free hemorrhage more or less severe occurred, which was never to be looked upon lightly and which might prove fatal. (7) The loss of blood might be through one rapid fatal hemorrhage or there might be a series of lesser hemorrhages. (8) If the patient did not succumb to loss of blood the presence of the blood and the ovum in the abdominal cavity acted as irritating foreign substances leading to loss of function and pathologic changes in the viscera, and perhaps to local or general infection, thrombosis, embolism, etc. (9) The dead ovum was only slightly less harmful from the standpoint of infection. (10) A study of the pathology made all treatment looking toward killing the ovum appear irrational. (11) Patients in good condition with or without ruptures were almost certain to have future trouble and should have an operation as soon as was consistent with good work. (12) Patients in bad condition with concealed hemorrhage from the cause in question had collapse in proportion to the amount of blood lost, and rational treatment must look with certainty toward the stopping of further hemorrhage. (13) An opening of the abdomen with clamping or ligaturing of the vessels was the only reliable means of controlling internal hemorrhage, and if done rapidly and with care was little tax upon the patient. (14) The clinical experience of the world and a study of the pathology of this condition pointed to the danger of delay. (15) The more desperate the case while the patient yet lived, the greater the call for immediate action.

#### DISCUSSION.

Dr. Edwin Walker, of Evansville, Ind., stated he fully agreed with the essayist, and so far as his personal knowledge went, he knew of one death from repeated hemorrhages; but most of the deaths had been in delayed cases in which sepsis had occurred after operation. The teaching that they should wait in these cases was not sound. He felt that the position taken by Robb was untenable. Those patients that had been operated upon promptly, in his experience had recovered.

Dr. Joseph Rilus Eastman, of Indianapolis, Ind., stated this was 1910, and it was a pity that it was necessary for Dr. Barrett to present a paper like the one he had read. The teaching that it was wise to allow a woman to bleed into her own abdomen, or into her tube or uterus, while the surgeon stood by with his arms folded and fell back upon soft pillows or relied on Providence, was absolutely pernicious. If a vessel were bleeding upon the surface of her body, what man would be so negligent or so indolent as to stand by and allow her to bleed to death?

Dr. Charles Stoltz, of South Bend, Ind., stated he thought the more energy they expended in teaching that these conditions were to be met and not dallied with, the better. The men who had received the proper teaching would recognise these conditions, and they would usually find some one who was competent to meet the conditions speedily, or they might be competent to operate themselves, because if there was any delay, or if the patient was carried from one place to another, she might just as surely die in one community as another. He did not know Robb, who said that shock meant nothing but hemorrhage, but if he made that statement, he wanted to forget it, as he would rather act upon the theory that shock was hemorrhage, and hemorrhage was shock.

### SPECIAL POINTS IN ADVANCED EXTRA-UTERINE PREGNANCY.

Dr. Shelby C. Carson, of Greensboro, Ala., stated in this paper he directed special attention to the control of hemorrhage during the operation. Although his experience was nil, he ventured the suggestion that the operation for advanced extra-uterine pregnancy be done in two stages when necessary or advisable, at an interval of forty-eight to sixty hours, according to the judgment of the operator. In the first place, let the abdomen be opened, the child delivered, the iliac tightly compressed by metal bands, and further, to be doubly sure, the ovarian and uterine arteries clamped by rubber-covered forceps, if they could be approached. In the second stage, separate the sac, release the blood vessels after ligating the anomalous ones and closing the abdomen. Sometimes hysterectomy was imperative. This differed from and apparently was superior to the old method of uniting the sac to the incision and waiting weeks for its separation, since by this method the danger from sepsis was eliminated.

#### DISCUSSION.

Dr. J. H. Carstens, of Detroit, Mich., stated he had one woman that went to term, a general practitioner having made the diagnosis. He operated on her in two stages. The placenta seemed to be attached to the intestines and the rectum, and he did not have the courage to remove it. He thought the best thing would be to leave the placenta alone, and so he removed the fetus, separated the peritoneum with the sac and drained. The woman was septic at the time of operation, and finally died from sepsis. The placenta did not separate. Little shreds came away through the abdominal incision.

Dr. William M. Harsha, of Chicago, stated he had never heard satisfactorily explained the cause of the intense pain that came on in cases of tubal rupture.

The extent of pain and the broad radiations of it were great in comparison to the very small area apparently involved. A woman with tubal rupture suffered pain from her chest to her thighs, sometimes at least. The broad radiations, with the intense character of the pain, made it almost impossible to get from these patients a rational explanation or history. These were the cases in which he believed a good dose of morphine was indicated. It would first abolish the cardinal or reflex pains to a certain degree and helped to localize the trouble. Second, it would limit the hemorrhage, but before administering morphine one should observe carefully the character of the pain, the extent of the radiations, the time, and the urgency of the condition. After recognizing these, morphine would answer two indications, namely, to relieve the shock and put the patient in a better condition for operation, and to some degree arrest the hemorrhage.

DR. CHANNING W. BARRETT, of Chicago, said in regard to dealing with extra-uterine pregnancy that was advanced, they found that in the early months the ovum was not considered. The probabilities were that so far as the ovum was concerned it would die, and the chances were that it would kill the woman sooner or later. A few years ago they would have said that at any time during the extra-uterine pregnancy, early or late, the ovum should be removed at the earliest possible moment. The teaching had been that if the ovum had passed the fifth month, or along about there, they should wait for viability. He would be inclined yet, even in spite of the teaching, to remove the ovum when found, if it had reached a viable period, looking to the interest of the child and mother.

### REQUIREMENTS AND LIMITATIONS OF NITROUS OXIDE AND OXYGEN ANESTHESIA.

DR. CHARLES K. TETER, of Cleveland, Ohio, stated the greatest advancement in general anesthetics made in recent years had been the development and use of nitrous oxide and oxygen in major surgery, and in general surgery he had seen within the past few years nitrous oxide and oxygen come from a very limited use to one of almost unlimited application. He had been one of the foremost in advocating the superiority of nitrous oxide and oxygen as an anesthetic. He had been compelled to do so because of the almost phenomenal success he had had with it. He had administered nitrous oxide and oxygen over sixteen thousand times in all conditions and for almost every conceivable operation, and having had this practical experience, which alone was essential to appreciate the excellency of this agent, he wished to give the profession the benefit of it. It was freer from post-anesthetic complications than any other general anesthetic known. It was by far the most difficult general anesthetic to administer because of the following reasons: (1) The physical properties of nitrous oxide were such that this gas must be given from eighty to ninety per cent pure, in order that a sufficient saturation of the gas in the blood might be had to produce that change in the nerve cell which brought about the anesthetic state. (2) The anesthetic properties of nitrous oxide and oxygen were extremely evanescent. The patient could pass from complete surgical anesthesia to a conscious state within sixty seconds. The extreme rapidity of induction and elimination made the administration of this anesthetic difficult. (3) Muscular tone was maintained to a much greater extent than it was under ether or chloroform, due probably to an increased per cent of carbon dioxide in the blood.

The requirements for the proper administration of nitrous oxide and oxygen were: (1) A thorough understanding of the technic of administration and action of nitrous oxide and oxygen. (2) The apparatus must be accurate, have attachments for the administration of other general anesthetic agents, and easily sterilized.

#### DISCUSSION.

DR. L. W. BREMERMAN, of Chicago, stated that in his special work, which dealt entirely with the bladder, the ureters and kidney, or conditions involving the genito-urinary tract, he had employed as a general anesthetic a combination of nitrous oxide gas and oxygen exclusively during the last two or three years. As it became necessary to perform major surgical operations upon the aged, particularly for the removal of the prostate, he could not recommend more highly any other anesthetic than the use of nitrous oxide gas and oxygen. It produced none of the untoward or after effects, such as nausea and vomiting. The patient was usually awake before he left the operating room. It had a great tendency to reduce the shock of the operation by shortening the length of the anesthetic, and in his hands it had given perfect satisfaction.

DR. FENTON B. TURCK, of Chicago, stated some years ago he conducted a series of experiments on animals with chloroform and ether with a view of determining the changes that occurred in the blood. It was found by these experiments that there was a loss in the antibodies and ferments in the blood, and that there was diminished resistance to bacteria, as was shown by the agglutinins, precipitins and other substances which were found in the antibodies in the blood. It was found that these animals went into shock very easily in which there was a lowered condition of the blood. These experiments showed the effects of ether and chloroform on the serum itself, and two conclusions were arrived at, one being that there was an actual direct chemical effect on the serum, and the other was that biological changes took place and acted on the cells as toxins.

### FURTHER OBSERVATIONS IN ACETABULAR FRACTURE WITH INTRAPELVIC OR CENTRAL DISLOCATION OF THE FEMORAL HEAD.

DR. WILLIAM FULLER, of Chicago, detailed two very interesting cases of this class of fracture and presented for consideration a few points in a general way pertaining to this important but, as yet, imperfectly understood subject. So close was the relation between fractures and the changes that took place in the bone, whatever they might be, that all such injuries resulting from trivial or slight degrees of violence should be regarded as possibly belonging to this class. Efforts had been made by several observers to put the etiology of fractures on a physical basis by studying the mechanical capabilities of bone. The great strength of the pelvic bones, their peculiar and powerful articulations and liberal muscular supply were factors which singly and combined contributed much to the neutralization of all forms of direct violence exerted on this portion of the body. While Katz's theory of the mechanism of certain acetabular fractures would probably hold good, it was also worthy of mention that the experiments of Kusmin demonstrated that this fracture could or would not occur unless the force be applied with the femur in abduction. When the legs were kept parallel the acetabulum remained unfractured.

From impacted fractures of the femoral neck central dislocation of the femoral head might be differentiated by the age of the patient and the comparatively high degree of injury in the latter instance. The remarkably sunken appearance of the greater trochanter and its slightly altered relation to Nélaton's line were points which distinguished the dislocation. The certainty with which the femoral head might be palpated in

either of the anterior dislocations of the femur and its increase in length in the thyroid dislocation would serve to differentiate any one of these dislocations from a central one. In the dorsal dislocation, especially to one above the obturator internus tendon, the trochanter was far above Nélaton's line, the thigh was adducted, flexed, and the axis of the dislocated femur crossed the lower end of the opposite one. Moreover, in the simple dislocation all movements would be less free than when the head and neck occupied a central position. It was not intended that the symptoms of acetabular fracture as here given were to in the least minimize the importance of the radiograph, but that each and every manifestation of all hip injuries of whatever nature should be carefully and cautiously considered. In no instance should the clinical findings settle the diagnosis, as they were frequently misleading, and the conclusions based thereon should invariably be corroborated by the roentgenologist. In case of failure to replace the head of the femur within the acetabulum, operative interference may offer the only hope of satisfactorily dealing with such a condition; but the particular type of operation and the advantages to be gained by it would depend much upon factors opposing the reduction.

Dr. Fenton B. Turck, of Chicago, read a paper in which he described the rôle which the colon bacillus plays in acute and chronic dilatation of the stomach.

(To be continued.)

## AMERICAN PUBLIC HEALTH ASSOCIATION.

Thirty-Eighth Annual Meeting, Held at Milwaukee, Wis., Sept. 6, 7, 8 and 9, 1910.

(Concluded from No. 2, p. 62.)

### A CONSIDERATION OF VENEREAL PROPHYLAXIS IN THE U. S. NAVY FOR THE BENEFIT OF PUBLIC HEALTH OFFICIALS.

Dr. Charles N. Fiske, of Washington, D. C., stated about 50% of the enlisted personnel of the Navy had a venereal disease during an average of four years. During 1908, there were 4,681 original venereal infections which entailed a loss of service and expense for treatment of 106,526 sick days; there were 1,001 cases of syphilis, which represented nearly 7% of the total physical disability of the Navy for that year.

While the morale had steadily and vastly improved during the past ten years in other respects, the damage resulting from this class of affection had assumed such proportions four years ago that numerous medical officers no longer felt justified in waiting indefinitely for moral regeneration; they felt that military efficiency demanded activities promising more immediate results; they instituted personal prophylaxis by the use of antiseptic irrigation and inunctions following exposure and upon return to the ship or station. Certain results achieved caused the department nearly two years ago to authorise the extension of this work in connection with the customary educational propaganda, and distribution of confidential circulars throughout the service.

Sailors and marines did not contract venereal diseases from the Navy, but from civil communities which were as notoriously indifferent to venereal disease as they were to typhoid and other widespread infections. Military services had practised compulsory notification of venereal disease for years and expect civil authorities to undertake similar measures for control. The source of the Navy's 15,000 first enlisted recruits, and the destination of a similar number of men discharged each year, was the civil population; its statistics would indicate that one youth out of every six in the urban population between the ages of seventeen and twenty-four contracted a venereal infection each year.

Venereal disease had by no means yet been conquered in the navy, but there was evidence that its ravages were being materially lessened and that instead of encouraging vice through the hope of immunity, the margin of failure of this prophylaxis was sufficiently wide to deter an increasing proportion of the personnel from sexual indulgence. The desire for clean men on clean ships had been stimulated, and no sense of security had been engendered.

#### DISCUSSION.

Dr. Gardner T. Swarts, of Providence, R. I., stated last year, as president of this association, he took the liberty of appointing a committee to take up the subject of venereal prophylaxis, with the idea that the people of the country were prepared to receive instruction in these matters. These communicable diseases were preventable, and if boards of health were to conserve the public health, then these diseases should be put on the reportable list and steps taken to prevent their prevalence as far as possible.

Dr. J. S. Neff, of Philadelphia, stated he did not think it was possible to compel physicians to reveal the existence of these diseases among their patients, and they would not report this class of cases to health departments.

Dr. John N. Hurty, of Indianapolis, Ind., stated he believed that the road leading to the prevention of venereal diseases was the longest and roughest which hygiene and sanitary science had to travel. At this time, every tribe, every nation and people of the earth were thoroughly syphilised. Think of that, and now we were proposing to eradicate it. The first man to propose education to eradicate these diseases was Solomon, and he began five thousand years ago, and with education, such as he gave, and such as they proposed to give, these diseases had increased and multiplied. Until they put aside that prudery which now prevented them from attacking this problem correctly, and which prevented them from teaching the child about his sexual nature and procreation, they could make no progress. Let them begin with the child.

#### REMARKS BY COLONEL ROOSEVELT.

Col. Theodore Roosevelt, who was unable to address the Association at the Auditorium, as expected, went out to Whitefish Bay in an automobile and addressed the Association there. He said he regretted very much that he was unable to meet them that morning. He could not do so, for the reason that the schedule mapped out for him was three times as much as he could do.

Like any other man in public affairs, he was awake to the needs of the public health. It was necessary to join their efforts for the preservation of the public health. It was important not only to keep the health of the individual, but also to keep the health of the nation.

Yellow fever was a distinctive national problem. Several nationalities in the western hemisphere had dealt with it and must deal with it effectively to prevent the ravages of this scourge.

The question of dealing with the public health was a matter of the last two generations. One half a century ago comparatively nothing was known of diseases which were a scourge to the human race. About six

hundred years ago the black death desolated Europe, a disease which undoubtedly they could deal with now. Then it took off two thirds of the population of Europe.

He had just come from a trip to the middle of Africa, where disease ravaged mankind as it did their ancestors. He passed through regions where the sleeping sickness had to its credit over 200,000 deaths in one neighborhood.

The advances made in the medical profession during the last half century were incalculable. The work of the Isthmus of Panama could not have been done in its present shape a decade ago. They could not have grappled with disease as now.

The prime requisite in every nation was to have every man and woman an effective unit. They were dealing with the basic problem of citizenship. Men could not be good unless they were healthy.

He welcomed the delegates to this convention who came from foreign countries, especially from the Americas. In the two Americas they were solving the problem of living peacefully together. Their only rivalry, far different from Europe, was the endeavor to see which was best able to cope with the problems that confronted them all. He welcomed them as their rivals, who were doing all in their power to uplift and care for the physical well-being of the human race. [*Applause.*]

EXECUTIVE METHODS IN PREVENTIVE MEDICINE.

DR. HENRY B. HEMENWAY, of Evanston, Ill., stated health administration was formerly local in nature. The science of public health had now advanced far beyond administration, especially in this country. The American law required a separation of the three branches of government. Health administrators, being of the executive branch, had no legislative power. They might not, however, issue any orders or regulations except as distinctly provided in the laws under which they were acting. All health authority was derived from the police power of the state. Police power was a system of precaution for the prevention of crimes and calamities. It was a necessary but also a dangerous power; and because of the danger to individual liberty, the courts were inclined to scrutinize its operations closely to prevent abuse. The police of public health started from the idea of nuisance, and presupposed legislative determination in great detail.

Even though administered by municipal officers, public health work was essentially state in nature; and in the absence of special constitutional provisions to the contrary, the state had the right to appoint and regulate the acts of municipal health officers. The protection of the state against damage suits was extended to all health officials, so long as they acted within the law, even though error had been committed, and damage resulted to individuals. As compared with other countries, American state executives were ill-organized and weak, and one of the weaknesses was shown in the tendency to the appointment of boards, often serving without pay. Since executives had no legislative power, an executive board lacked in responsibility, decision, activity and despatch, without compensatory advantage. There was no more reason why a physician should donate his public health service than that a lawyer should serve without pay as a judge, or a banker should give the use of the money needed for public improvements. Health laws should be enacted by the state legislature. The entire health administration of a state should be recognised as one body, having a single head to whom all local and district officials were responsible. Every man should be held responsible for a definite portion of the work.

Executive duties were either ministerial or discretionary. If ministerial, the officer might only do that which was required. If discretionary, he might do anything within that discretion; but neither his acts nor legislation for his guidance might be arbitrary or unreasonable. If the officer acted beyond the provision of the law, he might be sued as a private wrongdoer. Health legislation should be definite, not in general terms, to best safeguard individual liberty.

Matters of technical detail in the work of the office might be largely left to subordinates, but the executive must personally and frequently decide upon questions of administration. Such knowledge of administrative law as would give confidence in execution, celerity of decision and definiteness of effort would increase effectiveness. In other words, the head of the department should be a professional administrator with a broad knowledge of sanitary science, not merely a sanitarian or a party politician. At least once a year there should be a conference of state and district officers, at which proposed legislation might be discussed and prepared for presentation to the legislature for enactment.

DR. C. A. HARPER, of Madison, Wis., discussed the relation between state and municipal boards of health, saying the interchange of ideas, and the knowledge required by each health officer in knowing how other health officers did their work and met certain emergencies, fully justified the labor and expense incident to holding state or district conferences. If the health officer expected to impart knowledge to others, he must know his subject thoroughly and realize the important rôle which sanitation and public hygiene play in the prevention of diseases.

PROF. E. H. BAILEY, of North Dakota, spoke of the advantages of co-operation between the state board of health and state universities.

DR. GUSTAV F. RUEDIGER, of Grand Forks, No. Dak., spoke of the relation of the state university of North Dakota to the state board of health, and favored placing the state board of health laboratory under the control and regulation of the state university, under the direction of the professor of bacteriology and pathology.

DR. CHARLES A. HODGETTS, of Ottawa, Canada, pointed out the functions of the Canadian Commission of Conservation and Public Health.

DR. H. W. HILL, of Minneapolis, Minn., spoke of the relations of universities to public health work.

MAYOR SEIDEL, of Milwaukee, Wis., discussed social economics and public health. He said that land had a value. Timber had a value, and so had water and mineral deposits. These, with machinery, were important factors in wealth production. But the most important factor of all in wealth production was human labor. Without labor of hand and labor of brain applied to raw material, there was no civilization thinkable. The greatest of all natural resources was human life, with its accompaniment of labor. It was good and excellent work to conserve land and timber and water utilities, but it was far more important, and far more fundamental, to conserve human life and make it more efficient and give it added ability and power to create.

MR. FREDERICK ALMY, of Buffalo, N. Y., spoke of the inter-relation of national organizations working in the interest of health.

DR. FREDERICK MONTIZAMBERT, Director-General of Public Health, Canada, said the administration of the subject of public health in that country was joint between the Dominion and the Provinces. The administration of the subject of quarantine pertained solely to the Dominion government, including the

inspection and treatment of passengers, crews and vessels from abroad arriving at the different seaports on the Atlantic and Pacific coasts, and of the persons and trains entering Canada over the international frontier. Leprosy was dealt with by the federal government. The adulteration of foods and drugs was dealt with by the Department of Inland Revenue. Infectious and other diseases occurring within the Dominion were under the administration of the provincial and municipal authorities.

YELLOW FEVER HAD DISAPPEARED FROM THE MEXICAN REPUBLIC.

Dr. E. Liceaga, of Mexico City, contributed a paper in which he stated that from the twentieth of December of last year not a single case of yellow fever had been observed either there or in any other part of the Mexican Republic. In spite of the success obtained, the sanitary service continued its action with the same regularity as in previous years, although it was not directing its energies especially against malaria.

QUARANTINE OR ISOLATION IN DIPHTHERIA.

Dr. James Roberts, of Hamilton, Ontario, stated in this paper he first established the fact of the dominance of the personal contact factor in the spread of this disease. Defective drains, bad ventilation, etc., although prejudicial to health, cannot cause diphtheria, which was due to the presence of certain bacteria. Overcrowding assisted the spread of diphtheria. Forty-five per cent of his cases, representing not more than one quarter of the school population, came from the districts where the industrial classes were centered. The presence of an ignorant foreign element hindered the work of sanitation and favored the spread of disease. Diphtheria, owing to the manner by which it was spread, was a school disease. The Boston Board of Health, after an exhaustive investigation, concluded that it would be impracticable to isolate bacillus carriers who did not themselves suffer from the disease, as they constituted 1% of all healthy school children, and these germs were ordinarily of little virulence. The restriction of this disease was for practical purposes limited to isolation of clinical cases and control of the contacts in connection with these. Where isolation could not be strictly carried out at home, hospitalization was the best method. But isolation hospitals were very unpopular, owing to their usually poor equipment, the danger of cross infection, etc. They safeguarded the community, but often at the expense of the individual. Our present-day conception of diphtheria as pre-eminently a school disease made it imperative that the inspection of school children should be thorough enough for the detection of early cases, and of those children harboring virulent bacilli. When this had been accomplished, regulations intelligently enforced, providing for the proper isolation of all cases either at home or in suitable institutions, would be productive of better results and much less annoyance and hardship than the continued enforcement of antiquated laws and regulations incompatible with their present knowledge of diphtheria.

A STUDY OF THE VENTILATION OF SLEEPING CARS.

Dr. T. R. Crowder, of Chicago, Ill., stated the only available method of accurately estimating the air supply of running cars was by determining the amount of carbonic acid gas which their atmosphere contained, and from this computing the amount of air which entered. The problem was mathematically simple, and rested upon the known amount of carbonic acid thrown off by the respiration.

This method had been applied in the study of sleeping car ventilation. Some 2,000 samples of air had been analyzed from these cars. It showed that an average of approximately 40,000 cubic feet of air was supplied hourly to the main sleeping compartment of standard cars, which were equipped with the ventilating system now in common use by the Pullman Company, and that the amount was rarely, if ever, under 20,000 cubic feet. There were rarely more than twenty people in a sleeping car; hence each person was supplied with some 2,000 cubic feet of air each hour. This applied to the findings in occupied berths, both lower and upper, as well as to the car in which the berths were not made up.

The high wind pressure to which running railway cars were subjected resulted in fair ventilation even when they had no special ventilating devices. The amount of air which they received would vary from 15,000 to 50,000 cubic feet per hour, depending upon various conditions.

When cars were uncomfortable and felt "stuffy," the fault was not generally to be laid to an inefficient air supply, as was commonly supposed. It rarely happened that the air supply was so inadequate to bring about this condition, though it might at times contribute to it. The fault generally lay chiefly in an improper control and regulation of the heat supply. The degree of humidity of the atmosphere was also a very important factor; but its control was difficult, and often impossible. In the opinion of the author, heat control was a more important problem in maintaining comfort in sleeping cars than was the furnishing of a great air supply, and relatively greater attention should be concentrated upon this element of the problem and maintaining a hygienic atmosphere in cars.

Dr. John A. Amyot, of Toronto, Canada, discussed the laboratory in its relation to public health, while Dr. William A. Evans, of Chicago, spoke of efficiency and economy in municipal health work.

The Association endorsed the principles embodied in the Senator Owen Bill for the establishment of a National Department of Health.

A resolution was adopted recommending that a committee be appointed to consider and report next year a scheme (of which Dr. Probst shall be chairman) for instruction in hygiene and sanitation, in high schools, and in colleges and universities, with the view to bringing the necessity for such instruction, with definite recommendations, to the attention of educational authorities.

A new section to be known as the "Section on Sociology" was formed; also one to be known as the "Section on Sanitary Engineering."

The following resolution was adopted:

*Whereas*, A considerable number of municipal health officers believe terminal disinfection at the conclusion of communicable diseases is of questionable value and extravagant in practise; and

*Whereas*, A few municipal health officers of sound judgment and highest attainment have abandoned this practise as a prophylactic measure; therefore, be it

*Resolved*, That the Municipal Health Officers Section refer to the Executive Committee a recommendation that the American Public Health Association appoint a committee to study the end results and practise in communities where terminal disinfection is no longer practised at the conclusion of cases of communicable disease.

The following resolutions were likewise adopted.

*Resolved*, That this Association appoint a committee to co-operate with the Census Bureau in establishing standard methods of accounting for municipal sanitation.

*Resolved*, That this Association offers and accords

its hearty approval and commendation of the educational work carried on by the *Ladies' Home Journal* regarding the necessity and ways of teaching children the truth about reproduction and the sexual life.

OFFICERS ELECTED.

The following officers were elected: President, Dr. Robert M. Simpson, Winnipeg, Manitoba; First Vice-President, Dr. Fernando Lopez, Mexico City; Second Vice-President, Dr. John F. Anderson, Washington, D. C.; Third Vice-President, Dr. B. A. Bading, Milwaukee, Wis.; Secretary, Dr. William C. Woodward, Washington, D. C.; Treasurer, Dr. Frank W. Wright, New Haven, Conn.

Laboratory Section: Chairman, Dr. J. F. Amyot, Toronto, Canada; Vice-Chairman, Dr. John F. Anderson, Washington, D. C.; Secretary, Mr. B. R. Rickards, Columbus, Ohio; Recorder, Dr. H. D. Pease, New York City.

Vital Statistics Section: Dr. Wilmer R. Batt, Harrisburg, Pa.; Vice-Chairman, Dr. C. V. Chapin, Providence, R. I.; Secretary, Dr. F. L. Watkins, Columbus, Ohio.

Municipal Health Officers Section: Chairman, Dr. A. J. Douglass, Winnipeg, Manitoba; Vice-Chairman, Dr. Frederic Torralbas, Havana, Cuba; Secretary, Dr. E. C. Levy, Richmond, Va.

Havana, Cuba, was selected as the place for holding the next annual meeting.

## Book Reviews.

*State Board Examination Questions and Answers of Forty-one States and Two Canadian Provinces.* A practical work, giving authentic questions and authoritative answers that will prove helpful in passing state board examinations. Reprinted from the *Medical Record*. Third edition, revised and greatly enlarged. New York: William Wood & Co. 1910.

This new edition marks the third year of a well-known publication, which is sufficiently described by its title-page. It should prove a useful manual of review for new candidates for examination, and for practitioners obliged to be re-examined on removing to another state than that in which they were originally qualified.

*Movable Kidney.* Its Etiology, Pathology, Diagnosis, Symptoms and Treatment. By WILLIAM WELLINGTON, M.S. (Lond.), F.R.C.S. With 12 full-page plates and illustrations in the text. London, New York, Toronto and Melbourne: Cassell & Co., Ltd. 1910.

This excellent monograph presents the results of the author's personal experience with several hundred cases in which the diagnosis of movable kidney was made, in 230 of which he performed nephropexy on 350 kidneys. His results, so far as relief of symptoms is concerned, seem to have been admirable. He describes these symptoms under the headings of pain, and disorders of the alimentary, genito-urinary, and nervous systems. He also describes the technic of his own operative procedure. Though movable kidney should not be hailed as a cause of all obscure somatic disorders, and though its diagnosis should never be allowed to pass without rigid scrutiny and criticism, it is doubtless a definite pathologic condition, whose operative relief, as the author states, is precisely analogous to the radical cure of hernia. This volume states the observations and opinion of an expert in its study.

*Epidemic Poliomyelitis.* Report of the Collective Investigation Committee on the New York Epidemic of 1907. Octavo. Pp. iv, 119. With 14 plates. Nervous and Mental Disease Monograph Series No. 6. New York: The Journal of Nervous and Mental Disease Publishing Company. 1910.

This investigation was undertaken by committees appointed by the New York Neurological Society and the Pediatric Section of the Academy of Medicine, with the co-operation of Dr. Flexner, of the Rockefeller Institute; Dr. Bolduan, of the Department of Health of the City of New York, and Dr. Taylor as a representative of orthopædic surgery, and under the chairmanship of Dr. Sachs. Various subcommittees were appointed to study the epidemiology, the prodromal symptoms and the symptoms of the period of onset, the symptomatology and cause of the disease, the pathology and pathological anatomy, and the treatment. The committee estimated that the epidemic of 1907 in New York embraced about 2,500 cases, and they obtained positive knowledge of about 800 and a careful analysis of 752. The present volume, which presents the result of their labors, is the most important contribution to the study of poliomyelitis that has yet appeared, not only from the fact that it deals with the greatest epidemic occurrence of the disease yet known, but also because it presents the results of Flexner's studies of the communicability of the disease to monkeys by inoculation of the spinal cord from a case of poliomyelitis. The committee have established the fact that the disease is infectious, the symptoms of infection being sometimes as prominent as those of paralysis; that it may involve the lower part of the brain axis as well as the spinal cord, and that meningeal symptoms are usually common in the early stages of the disease; that it is more fatal than was supposed, and yet that recoveries are more common than was suspected. They believe that, although variations occur in the clinical type of the disease, there is no good reason for adopting Wickmann's suggestion of calling it Heine-Medin's disease, and they found that Strümpell's cortical polio-encephalitis was not observed in the epidemic. The committee certainly deserve the gratitude of the profession for their admirable work, which must remain an essential contribution for any further study of poliomyelitis, and a model for all future investigators.

THE BOSTON

# Medical and Surgical Journal.

THURSDAY, JANUARY 19, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 809 Paddock Building, 101 Tremont Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.*

*Remittance should be made by money order, draft or registered letter payable to*

W. M. LEONARD,
101 Tremont Street, Boston, Mass.

## IDEALS IN SEX EDUCATION.

Of all the problems that vex our questioning, self-responsible age, none is more perplexing, more profound, more protean, than that arising from the fact of sex. Indeed, it is not a single or even hydra-headed problem. As the instinct of sex is the most pervasive and imperious in human life, so its manifestations appear in every aspect of conduct and in all the possible relations of existence. There is no wonder, then, that from it have proceeded the greatest blessings and the greatest curses of mankind and that, sphinx-like, it still propounds the seemingly inscrutable riddle of the ages.

In earlier times, almost until the present day, it has been the policy of humanity to treat the darker aspects of this riddle by disregarding them, and it must be admitted that for the time there was something wholesome in this attitude. That time, however, seems now to be past, and one by one, for better or for worse, the problems involved in the relations of the sexes are being brought into the light for study and consideration. Probably it is well that this should be so, for the evils concerned lie at the root of civilized progress. The temptation is strong to leave their eradication to natural process, or, in Mr. Dooley's classic phrase, "turn the job over to destiny." But publicity is the watchword of the hour, and doubtless the free exposure of wrong is the first step towards its correction.

To many persons, perhaps to physicians especially, the grosser aspects of the problem present themselves most forcibly. The control, cure and prevention of venereal infections are tangible desiderata that are now frankly discussed and actively attempted. Yet though these be highly worthy of attainment, they concern objects which are after all superficial. Prostitution itself is but a symptom, not the real disease. To strike at the pathologic process one must influence the springs of human action, and the agent by which this may be done is not publicity, but education; and education should mean not merely preaching to adults, but teaching children by influence, suggestion and example.

That childhood is the time when the beginnings of evil may most easily be encouraged or suppressed has long been recognized. Unfortunately, the problem of teaching wisely to the young the facts and ideals of sex is so delicate, so subtle, that many shrink from attempting it, and those who are bolder seem often to have hastened the evils they sought to avert. At present the trend of policy seems rather towards an over-emphasis on the negative side of the proposition, a tendency to exaggerate the dangers and horrible consequences of sexual errors rather than to depict the inspiring nobility and blessings of the relations between men and women. Such measures fall as far short of the mark as bogie stories told to frighten children into obedience.

In an article on "Sex and Education," in the current number of the *Educational Review*, Mr. William D. Parkinson, superintendent of schools at Waltham, Mass., points out some of the inadequacies of such purely deterrent methods and suggests the sane and more hopeful methods of positive education in right attitudes and ideals. "To depict in startling colors the awful consequences of vice and to dwell upon its equally appalling prevalence," he writes, "have never been found effective in advancing standards of virtue." Nor is the inspiration of ideals into the receptive mind of puberty so difficult as might appear. Who cannot recall from his own experience chance suggestions that have been seized, perhaps subconsciously, and elaborated into motives of conduct and determining factors in life? There is considerable and credible evidence that good seed given the start has a certain tendency to grow and choke out the weeds that later are sure to spring up. To sow such seed should be the function of education, even more than to forebode the coming of the tares.

Doubtless the solution of the problems of sex might be left with some remote security to evolution, to "the long, hard grinding of the ages," to use Mr. Parkinson's expressive phrase. But, as Dean Briggs has said, the trouble with leaving the young to flounder is that so many perish pitifully in the process. We cannot afford to be too "careless of the single life." The fact seems

to be that sex is itself the most potent agent of evolution. Mere reproduction is not its object, because nature attains that end more successfully in other ways. The biologic reason for sex is to secure variation, which has resulted in the highest evolutionary processes of life. And based on sex, or rather appearing as its spiritual correlate or counterpart, are the intellectual and emotional functions which are the greatest glory of humanity. To physicians, prone, even compelled, to deal chiefly with the physical aspects of mankind, the possible exaltations and perversions of these functions are sometimes revealed as to no one else, and to them the suggestions of such a discussion as Mr. Parkinson's should bring reminders of the power which their position gives to their speech and example, and of the duty which they should share with the educator in teaching to the young and to adults ideals which their peculiar experience has to them most clearly revealed.

## THE MIGRATION OF HOSPITALS.

As a consequence of the growth of our larger cities, it is inevitable that many institutions should find their original locations unsuitable for their best work. In New York, for example, the march uptown of the churches has been noticeable during the past decade, a tendency at which a certain degree of criticism has been leveled, with what justice it is not our present purpose to decide. In the matter of hospitals, however, it is evident that light and space are both desirable, if not essential, for the proper care of the sick, and that neither of these is to be obtained in the crowded portions of a large city. St. Luke's Hospital moved to Morningside Heights some years ago; Roosevelt is about to follow, though not going so far, and now the New York Hospital, one of the most venerable of the city's institutions is planning a similar move.

It is announced that this hospital is to give up its present buildings on Fifteenth and Sixteenth streets, west of Fifth Avenue, and remove to a site, already purchased, on the bank of the Hudson River between Fifty-fourth and Fifty-fifth streets. There it is purposed to erect one of the finest hospitals in the world, the estimated cost of which, including land, buildings and equipment, will amount to more than $3,000,000. In the present buildings, in a closely built-up neighborhood, the supply of light and fresh air is more or less inadequate, and in deciding upon the new location the Society of the New York Hospital had in mind that congestion of population will never seriously affect the institution. To the south is the large DeWitt Clinton Park, on the west is the Hudson River, and eastward ample space will be afforded by the extent of the hospital grounds. It has excited some comment that a site should have been selected so near the Roosevelt Hospital, which is at Fifty-eighth Street, and only a short distance from the Hudson. The New York Hospital is much the oldest institution of its kind in the city, having been chartered in 1771 by King George III. The original site of the hospital consisted of five acres on what is now lower Broadway, and the foundations for the first building were laid in July, 1773. Before this was completed, however, it was almost destroyed by fire, and during the Revolutionary War the unfinished structure was used as a barracks by the British and Hessian soldiers. It was not until 1791 that the hospital was ready for the reception of patients. The institution was operated continuously until 1869, when, on account of lack of funds, its work had to be temporarily suspended; but later, through the income derived from leased lands, sufficient funds were secured to erect and maintain the present hospital buildings. Among the governors of the hospital in the past appear the names of John Adams, Aaron Burr, Thomas Buchanan, John Jay, James Duane, Frederick de Peyster, Cornelius Dubois, Augustus Van Courtlandt and many others well known in the history of New York. The branches of the hospital include the House of Relief, an emergency hospital on Hudson Street, New York, and the Convalescent Cottages and large Bloomingdale Hospital for the Insane at White Plains, Westchester County.

## PROPOSED MILK LEGISLATION IN MASSACHUSETTS.

BEFORE the Massachusetts State Senate last week a bill was introduced providing for the incorporation, in various communities, of medical milk commissions, which shall have authoritative general supervision of the milk supply in their respective districts, subject to the provisions of the State Board of Health. Some of the details of this proposed measure seem of sufficient importance to deserve quotation. It provides that:

"For the purpose of supervising the production of milk intended for sick-room purposes, infant feeding, for use in hospitals and for other uses, any five or more physicians authorized to practise medicine in this state may form a corporation subject to the provisions of chapter 125, Revised Laws. Members of the board of health in the city or town in which such corporation is formed

are to be members thereof *ex-officio*. Such corporation shall be known as the 'Medical Milk Commission' of such city or town.

"No member of such corporation formed under this act shall receive any salary or compensation for his services on such commission, nor any emolument or compensation from any dairy man or men producing milk under agreement with such corporation of any kind or character under penalty of a fine of $100 for each offense, to be recovered, as in any action for debt, by the corporation of which he is a member.

"The corporation so formed shall enter into agreements with dairymen for the production of milk under supervision of the Commission, and it shall prescribe conditions under which such milk shall be produced, the standards of purity and quality for certified milk as fixed by the American Medical Milk Commission and the standards for milk now or hereafter fixed by the laws of Massachusetts. The working methods of any corporation organized under this act and the dairies in which milk is produced under this contract shall at all times be subject to the scrutiny of the State Board of Health.

"No person, firm, association or corporation shall sell, exchange, offer or expose for sale or exchange as 'certified milk' any milk which does not conform to the regulations of the Commission formed under this act and which does not bear the certificate of a corporation organized under its provisions under penalty of a fine not exceeding $100 for each offense."

The intent of these provisions seems unquestionably good. It remains for adequate discussion and consideration to determine the practicability of such a system and the possibility of administering it without conflicts of authority and responsibility.

## MUNICIPAL HOSPITAL IN CAMBRIDGE.

A MOVEMENT has recently been set on foot in Cambridge, Mass., to secure funds for the establishment and maintenance in that city of more adequate hospital accommodations for the poor. A committee of twenty Cambridge physicians, organized to investigate and report on the need for such provision, issued last week the following circular letter, addressed to the citizens, embodying certain conclusions and recommendations:

"Though in some respects Cambridge is one of the leading cities in the Commonwealth, she has little reason to be proud of her record in caring for that unfortunate class which naturally appeals to the sympathies of every community — the sick poor. Aside from a few beds at the city almshouse, the only hospital accommodations in Cambridge for the care of patients suffering from acute medical and surgical diseases are provided by the Cambridge Hospital, which has but thirty-five beds for non-contagious cases. While this institution, equipped and supported by private funds, and the scanty fees paid by the less needy among its patients, is giving excellent service, it is manifestly incapable of coping with the needs of a city with a population of 104,000, a large proportion of whom are employed in shops and manufactories and are scarcely able to earn for themselves and their families more than sufficient to secure the bare necessities of life. No other municipality in Massachusetts of equal population is so poorly equipped with hospital facilities as Cambridge.

"Worcester, with a population of 145,986, has four hospitals, with 305 beds; Lowell, with 106,294, has two hospitals and 189 beds; Cambridge, 104,938, has one hospital and 35 beds; Springfield, 88,926, has four hospitals and 351 beds; Pittsfield, with only 32,121, has two hospitals and 157 beds; Salem, 43,697, has one hospital and 102 beds; Newton (also a suburb of Boston), 39,806, has one hospital and 115 beds; Fall River, 119,295, has two hospitals and 190 beds, and Waltham (another suburb of Boston), with one fourth the population of Cambridge, has two hospitals and 90 beds. In both Newton and Waltham these hospital facilities do not include their well-equipped contagious hospital, with a capacity of about 50 beds. The town of Arlington, with 11,187 people, has a hospital recently completed, with a capacity of 35 beds, the same as Cambridge, with a population about ten times as great.

"At this time the erection of a municipal hospital is being urged for economic reasons. The city is obliged to maintain a municipal and contagious hospital and has already appropriated the money for this purpose. By combining a municipal and contagious hospital under one administration, the city can save $10,000 yearly, thus in fifteen years saving the initial cost of a municipal plant. Moreover, the interest and sinking fund charges on a loan sufficient to build and equip a hospital of fifty beds would not exceed the annual amount now paid by the city to other municipal corporations for the care of the sick poor. The problem of a municipal hospital in a city with as large a population as Cambridge is inevitable. It must be met and solved in the proper manner. There is no more reason that Cambridge should neglect her sick than that she should neglect her parks or her schools."

It is admittedly the duty of every community to provide for the care of its medical dependents, that they may not become a burden on charitable institutions elsewhere. It is to be hoped that ways and means for such municipal provision may be satisfactorily found in Cambridge.

## PROJECTED ENDOWMENT FOR HARVARD DENTAL SCHOOL.

IT is announced that a movement has been instituted to secure for the Harvard Dental School an endowment fund of $500,000, to make possible

not only the continuance of its present educational work, but the extension of that work by the establishment of free clinics for poor schoolchildren, and the instruction of the public in the importance and necessity of dental and oral hygiene. For the purpose of obtaining this fund, a series of associated committees has been formed under the general chairmanship of Dr. Eugene H. Smith, dean of the Dental School. The organization of these committees is as follows:

From the administrative board: Dean Smith, Drs. Charles A. Brackett, Edward C. Briggs, William H. Potter, Harold DeW. Cross, Amos I. Hadley, Waldo E. Boardman, William P. Cooke.

Alumni Association: Drs. Harvey W: Hardy, F. T. Taylor, James A. Riley.

Harvard Odontological Society: Drs. Lyman F. Bigelow, Harry S. Parsons, A. H. St. C. Chase, James Shephard.

Dental School: Drs. John W. Estabrooks, Robert Whitehall, H. S. Parsons, E. B. Wyman.

Research Committee: Drs. Lawrence W. Baker, LeRoy M. S. Miner, H. C. Smith, George H. Wright.

Other graduates: Drs. Howard A. Clapp, Arthur H. Stoddard, Fred A. Robbins, Robert T. Moffatt, Evan P. Wentworth, D. F. Spinney, W. A. Davis, E. H. Coswell, Horatio E. Andrews, Robert S. Catheron, H. A. Lane, Reinbold Reulburg, Morris Peters.

The secure perpetuation of any good work depends on its adequate endowment, and if this can be obtained for the Harvard Dental School, its future should be as brilliant as its past has been distinguished and progressive.

## MEDICAL NOTES.

DEATH OF THE EMIR OF BOKHARA. — It is reported from St. Petersburg that on Jan. 5 Sayid Abdul Ahad, the Emir of Bokhara, a Russian subject state in Central Asia, died of bubonic plague.

THE EMPEROR WILLIAM RESEARCH FOUNDATION. — Report from Berlin describes the formal inauguration on Jan. 11 of the Emperor William Scientific Research Foundation, with funds equivalent to $2,500,000, the income of which will be used for the maintenance of two institutes for research in chemistry, as annexes to the University of Berlin.

INFECTION WITH DIPHTHERIA BY KISSING. — Report from Pittsburg describes the death from diphtheria, at Newcastle, Pa., of a woman supposed to have acquired the infection by kissing her brother as he was dying of the same disease. This fatality, which might probably have been avoided by the judicious use of an immunizing dose of antitoxin after exposure, serves to emphasize one of the many risks of indiscreet osculation.

A NEW SANATORIUM IN YORKSHIRE. — It is reported that the County Council of the West Riding of Yorkshire, England, has recently drawn up plans for the erection near Bradford of a new sanatorium for consumptives to accommodate fifty patients in permanent wards and fifty in temporary pavilions. The cost of maintenance of this institution is estimated at about six dollars a week for each inmate. Its work is to be extended by the establishment of a summer camp in connection with it.

A LAMENTABLE EXHIBITION OF RACE PREJUDICE. — It is reported that over a hundred white medical students at Georgetown and George Washington universities have refused to attend the lectures of one of their instructors because at a recent exercise of the class several negro students from Howard University were present. Such instances of race prejudice are unfortunate and unworthy in individuals of the supposed enlightenment of medical students.

FALSE STATEMENTS ON PATENT MEDICINE LABELS. — A case is now pending before the United States Supreme Court involving the decision "whether false statements on the label of a patent medicine as to its alleged curative properties constitute a misbranding punishable under the pure food and drug act," provided that the contents of the medicine be truthfully stated. The United States District Court for Western Missouri had recently decided, in the case of a "cancer cure," that such statements do not constitute misbranding. The reversal of this decision is sincerely to be desired, since whatever the legal technicalities, the intent of the law to protect the public seems obvious.

TWO NEW ITALIAN COMMISSIONS. — Report from Florence states that the Italian government has recently appointed two new royal commissions, the first of eight members, under the chairmanship of Dr. Alessandro Lustig, of Florence, to study the cause and transmission of pellagra, in the light of the views recently advanced in regard to it by Dr. Sambon; the second, of seven members, with Dr. Guido Bacelli, president of the sanitary council of Rome, as chairman, to investigate and report on the value of the shore

treatment of tuberculosis, with a view to the possible advisability of establishing and maintaining marine hospitals for patients with this disease.

Price and Supply of Radium. — It is reported from Paris that during the year 1910 1.92 gm. of radium were produced at Nogent-sur Marne, and sold for the equivalent of $153,600. The present market price of this valuable substance seems to range from $80,000 to $83,330 a gram, though it is stated that Sir Ernest Cassel recently secured a gram for the English Radium Institute for £15,000, the reduction being made "in consideration of the large amount purchased." It is said that the pitchblende mines at Joachimsthal, Austria, promise to afford a rich supply of radium, and the imperial Austrian government has recently placed them under control of the minister of public works, who is empowered to fix the price of all radium extracted therefrom.

Bubonic Plague in Asia. — Reports from all quarters indicate that the prevailing epidemic of bubonic plague is rapidly extending its ravages in northeastern Asia. Harbin, in Manchuria, appears to be the center of infection, and it is said that 600 deaths of the disease occurred there during the first fortnight in January. At Mukden there have been 30 deaths, and report from Blagovieshtchensk, Russia, states that in the province of Fudziadian there is an average of 80 deaths daily. The disease is also prevalent at Kirin, Kwanchongtse, Chang Chuen and Darien. The bodies of those who perish are thrown by the natives into the Amur River to carry the infection down its course. The Chinese and Japanese governments are, however, adopting measures to check the southward spread of the epidemic. A five days' quarantine has been established for all persons seeking to pass the Great Wall, and observation camps are to be instituted at Harbin, Mukden and Shanhikwan.

### BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, Jan. 17, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 46, scarlatina 44, typhoid fever 2, measles 51, smallpox 0, tuberculosis 71.

The death-rate of the reported deaths for the week ending Jan. 17, 1911, was 15.90.

Boston Mortality Statistics. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Jan. 14, 1911, was 222, against 237 the corresponding week of last year, showing a decrease of 15 deaths, and making the death-rate for the week, 16.80. Of this number 119 were males and 103 were females; 217 were white and 5 colored; 116 were born in the United States, 99 in foreign countries and 7 unknown; 42 were of American parentage, 146 of foreign parentage and 34 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 52 cases and 2 deaths; scarlatina, 41 cases and 0 deaths; typhoid fever, 5 cases and 1 death; measles, 41 cases and 1 death; tuberculosis, 98 cases and 24 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 28, whooping cough 1, heart disease 31, bronchitis 9. There were 13 deaths from violent causes. The number of children who died under one year was 25; the number under five years, 34. The number of persons who died over sixty years of age was 77. The deaths in public institutions were 85.

Conviction of an Illegal Cocaine Dealer. — Last week another illegal dealer in cocaine was trapped and arrested in Boston, and later sentenced by the district court to six months' imprisonment.

Fine for Violation of Pure Food Law. — At Malden, Mass., last week, a provision dealer of that city was convicted by the local court and fined $25 for violation of the pure food law in selling mixed pickles containing alum without noting that element of their content in the label on the packages in which they were dispensed.

Recent Seizures of Frozen Eggs. — On Jan. 12, ten cases of frozen eggs, each case containing two ten-pound cans, were seized by the United States deputy marshal at Boston as containing decomposed animal matter. The eggs, which were shipped from a firm in Chicago, were intended for use by bakers.

Report from Hartford, Conn., states that the United States circuit court has recently returned a verdict in favor of the government in a case in which conviction was asked for the shipment of 3,000 lb. of frozen eggs.

Work of Women's Municipal League. — At a meeting of the Women's Municipal League, held in Boston last week, the opening address was made by Dr. Richard C. Cabot in regard to the work done by the League in the care and education of women during pregnancy. During the

past year six hundred and twenty such patients were visited and instructed by the nurse provided through the agency of the League. Other addresses on the details and value of this work were made by Dr. Franklin W. Bock, of Rochester, N. Y., and by Dr. Robert L. DeNormandie, of Boston.

DUTY OF PHYSICIANS IN SEX EDUCATION. — At the annual meeting of the Unitarian Club of Boston, held last week, addresses were made on the subject of "Sex Education and the Family" by Dr. Frederick H. Gerrish, of Portland, Me., and by Dr. Prince A. Morrow, of New York, president of the American Federation for Sex Hygiene. Both speakers emphasized the responsibility of physicians in such matters and lamented their frequent apparent indifference on the subject. It should be added, however, that much yet remains to be done in defining more accurately the respective functions of physicians, parents and school teachers in such education.

FINE FOR FAILURE TO REPORT OPHTHALMIA NEONATORUM. — In the issue of the JOURNAL for Jan. 5 we reported the fining of a Boston physician for failure to notify the board of health of a case of ophthalmia neonatorum. Last week, before the East Boston Court, another physician of that district was fined $50 for the same offense of omission. Prosecution and conviction in such instances are the only means by which professional neglect can be checked and the enforcement of wise sanitary provisions insured.

SHORT-MEASURE MILK JARS. — Among other recommendations in the recently submitted annual report of the Massachusetts State Commission of Weights and Measures is one for the enactment of a law requiring that all receptacles in which milk is sold shall actually hold the amount which they are supposed to contain. The desirability of honest measure in this respect would seem to be self-evident. As a matter of fact, the commissioner has found that "many of the bottles now in use are short measure and result in a loss to the consumer of one-half cent on each bottle purchased." It is discouraging that all forms of honesty apparently need to be made matters of statute.

FOUR CENTENARIANS. — Abner Dunton, who died on Jan. 12, at Lincolnville Center, near Rockland, Me., was said to have been born on Aug. 1, 1807, in Barrettown. He is survived by two sons.

Mrs. Rebecca Gilmore, who died at Camden, N. J., on Jan. 10, was said to have been born on April 5, 1810.

Mrs. Anastasia Carey, alleged to have been one hundred and nine years of age, died on Jan. 10 in Philadelphia.

Samuel Tenover, who declared himself to be one hundred and nine years old, died last week near Danville, Ill. He was irregular in his diet and habits, used alcohol and tobacco and always had excellent health until shortly before his death.

LECTURE ON SYPHILIS. — Dr. Abner Post will repeat the public lecture on Syphilis, given in the Harvard Medical School course, on Sunday evening, Jan. 22, at eight o'clock, in the amphitheater of the Administration Building, Harvard Medical School. The lecture will be open to the medical profession and to nurses.

The repetition is at the request of the committee on public lectures.

COMMITTEE ON PUBLIC HEALTH OF THE SUFFOLK DISTRICT MEDICAL SOCIETY. — In conformity with the vote passed at the meeting of the Society, Oct. 29, 1910, a committee on public health has been appointed by the president. The members of this committee are Drs. E. G. Cutler, H. D. Arnold and L. R. G. Crandon.

It is hoped that this committee will be of very considerable service to the Society, and that it will represent the Society in all matters of medical importance in the city of Boston. Already the committee has shown its possibilities in putting itself on record as favoring the continuance of the School for Tuberculous Children in Franklin Park for one year more, as an experiment. This is merely a sample of the kind of service that the Suffolk District Medical Society, with its membership of nearly eight hundred physicians, can render through this committee in the cause of the public health.

MEETING TO DISCUSS MILK QUESTION. — On Jan. 16 a public meeting was held in Boston, under the auspices of the Boston Co-operative Milk Producers' Company, for the general discussion, by producers, consumers and physicians, of the much-vexed problems of the milk supply. The following was the program of addresses:

11.30 A.M. "Some of the Problems Confronting the New England Farmer," by H. G. Deane, Grafton, N. H.

11.50 A.M. "The Dealer's End of the Business," by I. S. Whiting, Boston.

12.20 P.M. "The Milk Dealer's Obligation to

the Producer and Consumer," by C. H. Hood, Somerville.

1.30 P.M. "Cost of Production," by Prof. J. W. Sanborn, Gilmanton, N. H.

2.10 P.M. "Inspection," by Dr. Richardson, Secretary State Board of Health, Boston.

2.35 P.M. "The Value of Milk as a Food Product," by Prof. S. W. Washburn, Agricultural Experiment Station, Burlington, Vt.

3.30 P.M. "Transportation," by W. A. Graustein, Cambridge.

### NEW YORK.

FUND TO PROMOTE RESEARCH. — By the will of Dr. Albert Seessel, of New York, who died on Dec. 24, his residuary estate is left for the establishment at Yale University and at the Koenigslich Sachische University at Leipsic of a fund to promote original research, to be called, in honor of his mother, the Theresa Seessel Fund. Among other bequests in the will are $1,000 each to St. Mark's Hospital and the German Medical Society of New York.

NEW YORK STATE HOSPITAL FOR THE CARE OF CRIPPLED AND DEFORMED CHILDREN. — At the regular meeting of the Board of Managers of the New York State Hospital for the Care of Crippled and Deformed Children, at West Haverstraw, N. Y., held Jan. 10, 1911, Dr. John Joseph Nutt was appointed as surgeon in chief to the hospital *vice* Dr. Newton M. Shaffer resigned. It is Dr. Shaffer's intention to devote himself to the future development of the hospital, as the chairman of the executive committee of the board of managers.

EXTENT OF CHARITABLE RELIEF. — The subcommittee on charities of the Commission on Congestion of Population has just made an elaborate report in which it states that at least one in every nine of the population of New York is the recipient of some form of charitable relief. In speaking of medical charity it says: "There are about 135,000 people constantly sick in New York, about 1 out of every 40, and 389 institutions to provide relief for the sick, with 259 in the congested boroughs. In spite of this careful provision, every year about 27,000 people die of preventable diseases."

COST TO THE STATE OF THE INSANE. — In his first message, sent to the legislature on Jan. 4, Governor Dix, in referring to the cost of caring for the insane, makes the following statement: "In the budget made up for estimated expenditures for this fiscal year the enormous sum of $8,660,281.38 is put down for the state care of the insane, and, while we owe a duty which cannot be questioned and must be strictly lived up to, of caring for those of our people who are thus afflicted, great care should be taken to see that the people are not imposed upon and that wasteful and extravagant habits of expenditure are not permitted to creep into the public affairs of the state. In this connection I would urge upon your attention the necessity for establishing a central department or bureau for the purchase of supplies, not alone for this department, but for all the other branches of the government which need to enter the market from time to time for the purchase of materials of various kinds. The revelations recently made as to conditions at Ward's Island and at some of the asylums for the insane show plainly the necessity for the existence of such reform, and indicate as well the great good that could be accomplished by it." It is also reported from Albany that the governor will shortly recommend that the present State Commission in Lunacy, consisting of three members, shall be abolished and that its powers be vested in a single commissioner.

2. Cragin and Hull, discussing the treatment of eclampsia, consider that the products of metabolism requiring elimination should be reduced by diet. Elimination of metabolic products should be favored by diuresis and catharsis. High blood pressure should be reduced, not by venesection, but by the use of nitroglycerin or veratrum viride. If the toxemia of the patient, as shown by the urine, blood pressure and general condition does not markedly improve under the preceding principles of treatment, or if an eclamptic seizure occurs, the uterus should be emptied. In all methods of treatment care should be taken not to lower the patient's resistance or seriously injure any of her organs. In this latter connection animal experimentation has shown that ether as an anesthetic is much safer than chloroform, as it, the former, produces practically no effect on the liver or kidneys as compared with the very marked changes produced in these organs by chloroform.

3. Davis and Foulkrod consider that eclampsia is a distinct disease, with varied manifestations and a definite pathologic picture. There is some relation between the fact that an altered nitrogen ratio is found in the excretions and the fact that the liver is the organ most seriously involved. A study of this progressive nitrogen disturbance may provide a guide as to the point beyond which the liver involvement cannot go and allow regeneration and recovery. While no placental theory has yet been proved, the most plausible theory is that some ferment from the placenta may prove responsible as a primary cause for the condition because of a deficient or deranged action. Any pre-existing permanent pathologic condition may prove an exciting cause and still perhaps act by disturbing placental function.

7. Hatcher and Bailey have been unable to obtain any evidence that the true Mexican cactus grandiflorus possesses any pharmacologic action whatever, but seems to be a singularly inert substance when administered by mouth or by vein. When colossal doses are given by vein they sometimes, but not always, appear to exert an extremely feeble action on the heart, but this action is too slight to determine its exact nature. Even the most colossal doses given by mouth to cats, dogs and frogs produce no perceptible effect. They assume, therefore, that any substance extracted from this cactus would likewise prove inert.

14. Chace, reviewing pyelitis of pregnancy, finds that the right kidney is more often affected; the infections by gonococcus, pyogenic organisms, bacillus coli communis and tuberculous germs are the commonest causes. Premature labor occurred in four of Swift's forty collected cases, and in Opitz's series seven out of sixty infants born died immediately or were stillborn. Treatment is as follows: Absolute rest in bed; fluid, preferably milk, diet; mild catharsis and hexamethylenamin in 0.5 gm. doses every three hours, and posture to relieve the ureter on the affected side. The interruption of pregnancy is seldom indicated. Autogenous vaccines have proved beneficial in certain cases. Irrigation of the bladder is beneficial to relieve symptoms, but cases often do just as well without this. [E. H. R.]

1. Anders discusses at length the pathological conditions of the pleura in connection with pneumonia from the clinical point of view. He mentions pleurisy, principally of the plastic type, which he has known to precede the infection of the lung; fibrinous pleuritis, present to some extent in practically every case of pneumonia; serofibrinous pleurisy with effusion; and empyema. As to the relative frequence of serous and purulent effusions, statistics differ widely, but post-mortem evidence shows the serofibrinous type to be far more common than clinicians have recognized. Serous effusions are relatively more frequent in adult cases, and purulent effusions strongly predominate in young children. The clinical evidence of these conditions is described according to the usual teachings. Two hundred and eighteen collected cases of empyema are analyzed to determine the time of onset; in 66 of the 218 the empyema appeared before the crisis of the pneumonia, or as a complication, whereas in 152 it developed after the crisis or as a sequel. In localized empyemas stress is laid upon Musser's sign, tenderness on deep pressure in intercostal spaces. In interlobar empyema the value of x-ray evidence is shown. Exploratory puncture, preferably with a small needle and syringe, is the measure by which in positive cases conclusive proof is obtained, but it is stated emphatically that this is to be avoided prior to the time of crisis or the beginning of resolution of the hepatized lung, and in treatment, even of empyema, delay of operation until resolution of the lung has progressed considerably is advised, relying upon simple aspiration to relieve pressure symptoms, particularly displacement of the heart.

2. Friedenwald and Ruhräh recommend the use of the soy bean, obtained from a leguminous plant cultivated extensively for food in China and Japan, as an article of diet for diabetes. Beans grown in America have been shown to contain water 10%, protein 34% and fat 18%. They contain starch, sugar and dextrine equivalent to approximately 10% of starch. Gruel made from soy bean flour 6 oz. to the quart (salted and boiled fifteen minutes and the loss by evaporation made up by adding water) contains: Protein, 8.4%; fat, 3.6%; sugar, 1.8%; and 720 calories per ounce. Meat may be added to make broth. By mixing five parts of soy flour with one of wheat flour, giving a flour containing 20% carbohydrate and 36% protein, muffins can be made. Cases are reported where distinct advantage was obtained by substituting soy flour for the gluten flour previously used.

3. Barach calls attention to certain auscultatory phenomena which are explicable only by the assumption that sounds may be conducted to points somewhat distant from the seat of their production along the bones of the thorax. Such phenomena are the bronchial breathing heard at the acromion process of the clavicle, bronchial breathing heard over the cervical vertebræ and even the cranium, and the bronchovesicular breathing of the upper portion of the right lung.

4. Rudolf describes a new method of estimating the coagulation time of the blood by filling glass tubes of small caliber, kept at constant temperature in a thermos bottle, with blood, and measuring the time after which when these tubes are broken a thread of fibrin strings out between the broken ends.

5. Fox reports six cases in which he observed attacks of transient delirium cordis. Five of these later developed the permanent type of irregularity.

7. Macht has studied the mutual influences of tuberculosis and menstruation. In tuberculosis he notes that although some patients menstruate regularly to the end, a certain number have amenorrhea which may be preceded by menorrhagia. Dysmenorrhea of tuberculous origin may occur. In menstruation he finds an aggravation of all symptoms and an accentuation of all physical signs of tuberculosis. He describes periodic hemoptyses at the time of menstruation.

10. Kinney, as the result of an extensive experience with the Cammidge "c" reaction, concludes that its value is very limited. Neither a negative nor a positive result is conclusive. Very little dependence can be put upon a negative reaction, and a positive reaction can only be considered of value as a confirmatory examination.

5. Coley has reviewed the literature on the subject to date, adding 30 cases to the series collected by Norkes in 1893. Ten of these 30 are reported for the first time. He gives histories of a personal case, 1 of M. H. Richardson, 2 of Gilbert Barling, 1 of Hartley and 1 of W. W. Keen. Five other cases are given, personally observed but not operated on account of the extent of growth when first seen. The 63 cases are tabulated with reference to reporter, date, sex, age, side, site, duration, size, type of operation, type of growth, result, final report, trauma, concurrent disease, glands and mixed toxins. Macroscopic examination of the tissue, clinical history, physical signs and x-ray are sufficient, Coley believes, to those with large experience with bone sarcomata to justify total or partial excision of the clavicle without waiting for the result of microscopic examination. Inasmuch as recurrences in cases of sarcoma of the long bones generally are less than one third as frequent in cases in which mixed toxins have been administered than in cases in which they were not administered, he advocates their use as a routine prophylactic procedure immediately after operation. Antecedent trauma was noted in 7 of 9 cases personally observed. Of the 63 cases, the greatest number occurred in the second decade (19 cases). Six cases were well at the time of the last observation; 1 fifty years (Mott's case probably of central origin), 1 ten years (Wheaton's case, type not stated), 1 five years (Norkes's case of myeloid type), 1 two years (Richardson's case of periosteal type), 1 one and one-half years (Huntington's case of periosteal type) and 1 seven months (Coley's case of central origin). Eleven of the 63 cases died from the effects of operation. In 7 cases recurrence occurred within six months, 1 case recurred in one and one-half years, 1 in four years and 1 in nine years. Primary sarcoma of the clavicle is rare, requires very early diagnosis and very early radical treatment.

6. Owing to the frequency with which gastric cancers develop upon ulcers (71% of 263 cases at St. Mary's Hospital), William Mayo is convinced that chronic caloused ulcer of the stomach is best treated by excision. The difficulty of executing excision of ulcers on the posterior wall of the body of the stomach has been met by the following method of operating in 5 cases with satisfactory results. After opening the gastrohepatic and gastrocolic omenta above and below the ulcer, the ulcer surface is cut free, if possible, from the posterior attachments without opening the stomach. A piece of gauze is packed into the denuded area behind. (This produced hemostasis in 4 of the cases; in 1, vessel ligature was necessary.) The anterior wall of the stomach is then opened and with the fingers behind the entire ulcerated surface is pressed through the anterior incision and the ulcer excised. Gap closed with transverse through-and-through chromic sutures from the mucous side reinforced by several linen mattress sutures from the mucous side. Anterior wall closed. As a safeguard several rubber tissue drains are carried down behind the stomach and brought out at the upper end of the abdominal wound.

7. MacCarty and McGrath have studied at St. Mary's Hospital the condition of the appendix in operated and autopsied cases of gastric, duodenal, hepatic and pancreatic disturbances. Two thousand five hundred and forty-nine autopsies showed partially or completely obliterated appendices in pyloric spasm (17%), gastric and duodenal ulcers (26.9%), cholecystitis (52%) and cholelithiasis (44.8%). A study of the histories of operated cases with reference to the age at onset of symptoms, pain and soreness in the region of the appendix, and the age at time of operation, and a study of the condition of the appendices at operation further suggest the appendix as at least a part of the etiology of some morbid conditions of the stomach, duodenum and gall bladder.

10. "A satisfactory operation for undescended testis has at last been attained." So speaks Moschcowitz of the Bevan operation after employing it in 18 cases, 4 bilateral. The condition of the body of the testes, the epididymis, the vas deferens, the vaginal process, the spermatic cord, the spermatic vessels and the scrotum in cases of undescended testis are carefully considered. "The vas is always of ample length." "The spermatic vessels are poorly developed" and "are deficient in length." Herein lies the explanation of the uncertain or poor results following most operations; for they do not recognize that the deficiency in length of the cord is due to the vessels. Moschcowitz has tried nearly all the methods which seemed to him rational. These he describes and gives his results. The essential part of the Bevan operation is the division and ligation of the spermatic vessels, depending upon the artery of the vas for the nourishment of the testis. In no case did necrosis of the testicle occur, erectile power was to a certain extent preserved, all testes are freely movable and in the very bottom of the scrotum.

12. MacAusland and Wood review the literature on fracture of the tarsal scaphoid and add two cases of their own. In one of their cases the scaphoid was completely removed; in the other, only the displaced fragment. They prefer the former method. Reduction of the displaced fragment should, of course, be attempted before operative treatment. Immediately after operation the foot is placed in a light plaster cast in inversion for three to four

weeks followed by spiral strapping. A light spring plate is advocated to relieve the operated region from strain in weight-bearing. After six to eight weeks baking and massage are instituted. [T. W. H.]

10. VANSELOW. *The Disinfection Box for Midwives.*
11. *MARTIUS, K. *Local Effect of "606."* (Concluded.)

1. The writers discuss the theoretical explanations of herpes gestationis and report a case which yielded promptly to three injections of serum from normal pregnant women after having resisted many other forms of treatment. The eruption recurred after about five weeks of health and again yielded quickly to the same treatment.

2. Riehl studied the temperatures of the stomach and rectum in a series of ten patients before and after the application of cold externally to the abdomen. The results are given in a table showing the sex, weight, height and hemoglobin of every patient, as well as the temperatures before and after and the duration of every experiment. He obtained differences in the stomach temperature ranging between 0.5° and 1.8° C. In one case the rectal temperature did not change. The greatest rectal variation was 1.1°. He raises the question whether this procedure might not help to stop gastric hemorrhage either by change of temperature favoring clotting or by causing contraction of the capillaries.

11. Martius concludes in this number an exhaustive paper on the effect of "606" at the point of injection. His work includes the examination of several cases post-mortem. He says in the summary that after subcutaneous or intramuscular injections of the drug in any dose or in any solution all tissue which came in direct contact with it becomes necrotic. Necrosis of nerves may explain the frequent neuritic symptoms and perhaps the disturbances of the bladder. Necrosis of the skin apparently can be avoided by rightly choosing the point for injection. The necrotic tissue may slough off months later and arsenic may be found in it. In view of the rapid decomposition of the drug it is doubtful whether it can be absorbed slowly as from a depot, but harmful derivatives perhaps are so absorbed. The neighboring veins are always thrombosed. Severe deep necrosis may occur and infection may lead to death. (The summary is too long to be given in full.) [G. C. S.]

3. Hammerschlag gives a brief introduction stating the legal attitude in regard to such operations. He then takes up hyperemia gravidarum, heart lesions, phthisis and tuberculosis of the larynx, kidney diseases, including pyelitis, diabetes mellitus and chorea. In each of these he points out the definite indications for interruption of pregnancy and shows how rarely is this operation demanded. He presents statistics to support his statements. In conclusion he advises in all cases a consultation with a

specialist before the decision is reached to undertake this operation.

4. The author points out the complications in subsequent pregnancies which are liable to follow this operation — dangers to the fetus and to the mother during labor. He also describes different methods of operation and after-care which will give satisfactory results in subsequent pregnancies and also prevent pathological conditions returning after pregnancy and labor. 10. Faulhaber. *The Importance of Röntgen-Ray Investigation in Diagnosing Cancer of the Stomach.*
11. Weizsäcker, V. *Essay on the Velocity of the Blood in Anemia.*

2. Trembar reports a case of lymphosarcomatosis in which there was a positive Wassermann reaction. The diagnosis in this case seems sure and great effort was made to rule out syphilis from the history, autopsy, etc. Also, great care was taken in the Wassermann tests and many were tried. It certainly seems as though syphilis could be excluded and the positive serum reaction relied upon.

5. Massini reports on two cases of nitrobenzol poisoning. The blood pictures in these cases are carefully worked out. The blood picture was similar to the embryonal types of anemia seen in experimental anemias. This shows a sudden fall in red cells and suggests a destruction temporary at least of the blood-forming areas. The increase in white cells and swollen spleen are accounted for by rapid destruction of red blood cells.

During the acute poisoning there is dilatation of the heart and vessels causing gallop rhythm and a fall in blood pressure.

6. Meyer-Betz reports a case of hemoglobinuria associated with muscle weakness. The muscle weakness amounting almost to a paralysis would eventually pass off, but it would take weeks. Finally, signs of contracture appeared, although in a note of correction at the end he mentions that the man is now apparently as strong as ever, although evidence in the muscles of former injuries still persist. The hemoglobinuria differs from the paroxysmal type in that it is not produced by chilling and the characteristic hemolysin is not present. The patient had several attacks.

7. The Schmidt nuclear test has been tried out *in vitro* by this author, who obtained quantities of gastric and pancreatic juice. He concludes that pure gastric juice leaves tissue nuclei unchanged. Pure pancreatic juice dissolves nuclei completely in six to eight hours. Pure intestinal juice does not affect cell nuclei, and intestinal juice obtained by crushing may dissolve the nuclei. He thinks, therefore, that the Schmidt test is reliable.

[C. F., Jr.]

## Obituaries.

### JOHN FLINT, M.D.

Dr. John Flint, a grandson of Dr. John Flint, of Boston, died at the Naval Hospital at Chelsea, Mass., Jan. 11, at the age of thirty-four.

Dr. Flint was born in Peru, April 4, 1876, his father at that time being engaged there in railroad construction and management. Preparing for college at the Roxbury Latin School, he graduated from Harvard in the class of '98, He at once enlisted as a private in the Sixth Massachusetts Volunteer Regiment and served in Porto Rico. The following year he entered the Harvard Medical School, graduating in 1903 and later serving as a house officer at the Massachusetts General Hospital. In 1904 he was appointed an assistant surgeon in the navy, but resigned in a few months and went to Chicago to engage in practice. He re-entered the navy in the spring of 1906 and was stationed at Norfolk, Va., until the fall of that year, when he went to the Naval Medical School at Washington. From this post he was ordered in 1907 to the Naval Hospital at Cavite and later served on the gunboat *Wilmington* on the Chinese coast. Returning to America in 1909, he was ordered to the United States Naval Hospital in Philadelphia, and then in the autumn of the same year to the Naval Hospital at Chelsea. His membership in medical and allied societies included the Boylston Medical Society, the Aesculapian Club of Boston, and the Massachusetts General Hospital House Officers' Alumni Association. He was also a member of the University Club of Boston, the Harvard Club of New York and the Army and Navy Club.

Dr. Flint's untimely death is a matter of deep regret to his many friends and associates. Young as he was, his experience in the medical work of the navy was already broad, and there was great promise of a still more successful career in the future. His death will prove a distinct loss to the Service.

### CHARLES E. INCHES, M.D.

Dr. Charles Edward Inches, who died in Boston on Jan. 12, was born at East Boston on Aug. 31, 1840. He received the degree of A.B. from Harvard in 1861, and that of M.D. in 1865. While in the medical school he

served as a surgical interne at the Massachusetts General Hospital, and before his graduation was commissioned assistant surgeon of the Thirty-Seventh Massachusetts Regiment of the Sixth Army Corps. With this regiment he served until it was mustered out, and was then transferred to the Twentieth Massachusetts Regiment, with which he remained till the close of the Civil War. Returning to Boston in November, 1865, he began the practice of medicine and soon after was appointed physician to the North End Dispensary. In 1883 he was married to Miss Louise Pomeroy, of Troy, Pa. He was a Fellow of The Massachusetts Medical Society. He is survived by his widow, by a daughter, and by two sons.

### SEX AND EDUCATION.

BOSTON, Jan. 10, 1911.

*Mr. Editor:* May I call the attention of your readers to the article on Sex and Education by W. D. Parkinson in the *Educational Review* for January, 1911?

It contains, I think, more true wisdom on this topic than all the books and articles that have appeared within the past few years.

Very truly yours,
RICHARD C. CABOT, M.D.

### A CENTENARIAN.

WAREHAM, MASS., Jan. 16, 1911.

*Mr. Editor:* Since to attain the age of one hundred years is rather unusual and worthy of note, I wish to report to the JOURNAL that Mrs. Susannah K. Tobey, of this town, yesterday, Jan. 15, celebrated her one hundredth birthday.

Very truly yours,
CHARLES E. MORSE, M.D.

### APPOINTMENT.

DR. C. C. CRANE, formerly assistant in the Orthopedic Department of the Massachusetts General Hospital, and at present in the orthopedic service of the Children's Hospital in San Francisco, has been appointed assistant in orthopedics in the Medical School of the University of California.

### SOCIETY NOTICE.

THE BOSTON MEDICAL LIBRARY IN CONJUNCTION WITH THE SUFFOLK DISTRICT MEDICAL SOCIETY.—Medical Section meeting, John Ware Hall, Feb. 1, 1911, at 8.15 P.M. "The Climatic Treatment of Tuberculosis," Guy Hinsdale, M.D., of Hot Springs, Va.

EDWIN A. LOCKE, M.D., *Secretary*, 311 Beacon St.
HENRY JACKSON, M.D., *Chairman*, 380 Marlborough St.

### RECENT DEATHS.

INCHES, CHARLES EDWARD, M.D., M.M.S.S., died in Boston, Jan. 13, 1911, aged seventy years.

DR. DARWIN COLVIN, a prominent physician and surgeon of Wayne County, N. Y., who was graduated at Geneva in 1844, died at his home in Clyde on Jan. 8, in the eighty-ninth year of his age. He was at one time the president of the New York State Medical Association, of which he was one of the founders.

DR. LABAN L. BRADSHAW, of New York, died on Jan. 9, in his fifty-ninth year. He was graduated from Bellevue Hospital Medical College in 1880.

DR. HENRY RUTGERS CANNON, who died last week at Elizabeth, N. J., was born in New Brunswick in 1821. He had practised medicine for sixty-eight years.

DR. WILLIAM WOLFE LESEN, of New York, died from cerebral apoplexy on Jan. 11, in his thirty-third year. He was graduated from the medical department of Columbia University in 1903 and at the time of his death was visiting physician to the New York City Children's Hospital and Schools.

DR. JOHN P. GILBERT, of Lyons, N. Y., died on Jan. 8. He was born at Lyons in 1828 and was graduated from the New York University Medical College in 1856. He was at one time in charge of the Albany Eye and Ear Infirmary.

DR. EDWARD PAULDING, of New York, died from cerebral apoplexy on Jan. 10. He was a native of Kingston, N. Y., and forty-five years old, and was graduated from the College of Physicians and Surgeons in 1890.

DR. HILARY TUCKER SWEENEY, who died of heart disease last week in East Boston, was born there in 1866. He graduated from the Harvard Medical School in 1889, and since that time had practised medicine in East Boston. He is survived by his widow and by one child.

DR. WILLIAM GRIER, who died on Jan. 11, at Washington, D. C., was born in Ireland on Oct. 5, 1816. He was formerly surgeon-general of the United States Navy, and at the time of his death the oldest officer on its retired list.

DR. CHARLES JOHN KIPP, who died on Jan. 13, at Newark, N. J., was born in Hannover, Germany, on Oct. 22, 1838. He came to the United States in 1854, and in 1861 received the degree of M.D. from the College of Physicians and Surgeons, New York. From 1862 to 1866 he served as a surgeon in the United States Army. In civil practise he became distinguished as an ophthalmologist and otologist, and since 1880 had been surgeon to the Newark Eye and Ear Hospital. He was a member of the Ophthalmological Society of Heidelberg, of the New Jersey Medical Society, of the New York Academy of Medicine and of the New York Pathological Society. In 1907 he was president of the American Ophthalmological Society and in 1908 of the American Otological Society. He was unmarried.

DR. EDWIN F. VOSE, who died on Jan. 13, at Portland, Me., was born in Watertown, Mass., in 1850. He graduated from Boston University in 1876 and had been a resident and practitioner in Portland for over thirty years. He was for a time president of the Maine State Homeopathic Medical Society.

## Original Articles.

### HERBERT LESLIE BURRELL, M.D. (1856–1910). IN MEMORIAM.*

TRIBUTES FROM DRS. E. H. BRADFORD, F. S. WATSON AND GEORGE H. MONKS.

DR. E. H. BRADFORD: It was the custom of the Society of Medical Improvement, even in its earlier days, to hold memorial services in honor of its deceased members, and the practice is a commendable one. The standard of service of the medical profession in this community has always been high, and this society for nearly a century has had as its members many of the leaders of our profession. The custom, however, is one not to be too frequently observed. These occasions should never be made public demonstrations of the private grief of friends. The world has little use for mourning. It needs encouragement; examples to stimulate to greater exertion; it is, therefore, proper that those who take part in such occasions as these should show a warrant for their claim and for the justness of their request that a new name be placed on the honor rolls of this honorable society.

The mere mention of Dr. Burrell's varied services is an indication of his unusual qualities. For any one in a few weeks to have organised and equipped a relief ship is no small achievement, but it was the work of a master mind to have transformed a coaster into a model hospital ship, studied abroad and prized by the national government. Any one who had an opportunity to visit the hold of the *Bay State* on her return from Santiago with her precious cargo of fever-stricken Massachusetts soldiers, and to bear witness to the fact that the air even over the bilge keel was as fresh as that of the open ocean, and who saw a service and organization superior to that of the best of hospitals, could recognize the debt not only of the suffering Massachusetts soldiers, but that of the commonwealth, to this volunteer surgeon, who directed and commanded three expeditions of relief during that summer of anxiety and confusion. In a monarchy he would have been granted a knighthood, but in our simpler republic he won the highest of all rewards — of satisfaction in good work well done in a brilliant achievement for the larger aiding of humanity.

As a surgeon-general of our state he greatly increased the efficiency of the medical service of the militia and he left it a model in excellence of equipment.

His work on the Reception Committee for the Boston meeting of the American Medical Association placed him foremost among organizers for such undertakings, and in the reorganization of the Red Cross Society, in the establishment of the Society of Military Surgeons, as secretary

* Presented at the Boston Society for Medical Improvement (an Historical and Memorial Society), Nov. 14, 1910.

of the National Surgical Association, and as president of The Massachusetts Medical Society, he proved the high quality of his leadership. The presidency of the American Medical Association came to him as a well-won honor, but his careful plans for the advancement of the interests of that powerful organization were frustrated by the malady which brought his labors to an end.

These achievements, though unusual in character, do not represent the true measure of his service; they were the diversions, episodes in the career of a young man of energy and force. The chief purpose of his life was to aid in the development of the profession of surgery. As a medical student visiting a New York hospital, he silently pledged his energies to the advancement of that noble art. For him it was not alone the sick man who was to be aided. He endeavored to help the profession itself in such directions as seemed to need strengthening. He had little sympathy with those who made their calling chiefly an opportunity for personal vainglory, who used for personal gain their school or hospital positions. For him these positions brought with them a duty to the community and to the profession which he most loyally fulfilled.

The practice of surgery in America thirty years ago was excellent in quality, but there were marked defects in our hospital organizations which cramped the development of the average surgeon. Three months of active hospital surgical work and nine months of general practice did not offer the best chance for the training of surgeons of the greatest experience. It was early Dr. Burrell's endeavor to establish a continued in the place of the short service, then universal in American hospitals, and he succeeded early in his career in arranging a continued surgical service at the Boston Children's Hospital, although in the large civic hospital with which he was connected all of his professional life the establishment of a single continued service under one head was impossible. The grouping of services of a selected number of surgeons, graded according to skill and seniority, and working under one leadership, seemed to give an organization with many advantages. It furnished a stimulus from combined efforts with a single direction continued from year to year. This system was finally adopted largely through the efforts of Dr. Burrell.

The teaching of surgery, formerly consisting of brilliant lectures by surgical leaders, or clinics where the masters of their craft displayed their skill in rare operations to a sensation-loving class, needed to be changed. The careful study of patients, by small groups of students, who, under the direction of trained teachers, learn thoroughness of observation and skill of hand, presents a system of education which is of high excellence, but one which needs the enrollment of a number of earnest instructors, working less for personal advancement than from devoted interest in their profession. It was to the development of this system that Dr. Burrell gave the chief energies of his life.

Medical education twenty years ago was excellent, but the rapid growth of the sciences of medicine has made the problems of our medical schools much more difficult. When medical teaching was under the charge of the professors of a few departments, if each could attempt to make his course the most thorough possible, an excellent school resulted, but this system brought confusion to the average student when the departments became more numerous and there was no proper sequence or proportion in the instruction given. How earnestly and devotedly Dr. Burrell worked to perfect such a grouping and arrangement of courses as would give to the student some knowledge of everything that was needed for the practitioner, and an opportunity for the more thorough study of that group of subjects which was most important to each individual, is known best to the few who witnessed his self-sacrificing zeal and singleness of purpose. The subordination of the individual to the system and the perfection of that system was the creed of his endeavor, and we are to-day beginning to see the results of his labors. When he erred it was in the excess of zeal which at times led him to lose a nice sense of proportion. He may be said at times to have thought in too large print. A sonnet in scare lines or shouted in a megaphone is less effective than if presented in a more simple form or whispered to attentive rather than startled listeners. There was sometimes too much energy in his attack, and this aroused opposition, but something must be pardoned in the earnest. Peter the Hermit doubtless failed to use the tempered phrase, and those who labor in large undertakings have little time for the practice of milder methods. It was to the robustness of his effort and the vigor of his onset that Dr. Burrell owed the accomplishments of his energetic life.

This is the record which is presented to this society. It is a record to be studied. We admire those who work successfully advancing themselves, but we honor most those whose lives show a long struggle to help others. It is a record which can be made to serve as a stimulus in the hope that such years of effort may bring permanent results. It is a record the contemporaries of Herbert Leslie Burrell can applaud. It is a record that his friends can be proud of. It is a record which we can imagine that those masters of the past whose pictures look down upon us from the walls of this room dedicated to the best traditions of our profession we can fancy would rejoice in with their praise of "well done." It is a record as to which the words of the prophet Isaiah can be used in asking that we may "declare his doings, make mention that his name be respected, for he did many excellent things."

DR. FRANCIS S. WATSON: To have developed one's native attributes to the utmost of one's power, to have devoted them to the service of one's fellows in humane works, to have preferred serving good causes to the promptings of personal ambition, to have been intrusted

with offices of much responsibility involving a great amount of labor and to have discharged the duties belonging to them unfailingly, ably and thoroughly in every instance is assuredly to have made all that any man can make of his life and a great deal more of it than most men do.

Herbert Burrell did just these things with his life, and Death, in writing "Finis" on the last page of the record, closed an unusual career.

The titles of the principal chapters of the record read thus: Surgeon to the Carney Hospital, surgeon to the Children's Hospital, senior surgeon in chief to the Boston City Hospital, surgeon-general of the Medical Corps of the Massachusetts Militia, commander of the Hospital Relief Ship *Bay State* sent by Massachusetts to Cuba during the war with Spain, president of the New England Branch of the National Red Cross Association, president of The Massachusetts Medical Society, president of the American Medical Association, Homans professor of surgery at the Harvard Medical School.

In all of these important positions and institutions his influence was strongly felt, and in all of them improved conditions resulted from his efforts.

He began his career without the support of friends influential in the profession or the benefits derived from a college education. All that he achieved, all that he won, was due to his unaided energy, strength of character, steadfastness of purpose and self-training. In some measure doubtless his success is to be referred to the effort demanded to surmount the barriers that he encountered, for he was of those whose forces are fed by obstacles and whose resolution hardens in the face of difficulties.

He was properly ambitious and sought to secure the highly honorable positions to which he attained, but the wish for personal advancement never outran his desire for the general good, and in the thirty years of close association that I had with him I never saw Herbert Burrell prefer his own advantage to the best interests of a good cause.

His own words which I quote from a letter that he wrote to me some time since allow us to judge of his views with regard to what I have just said. The letter concludes thus: "There is a great work for us still in the future and I believe it to be this: That we shall strive to make this the center of the best surgery that is done in the world. Not that we can do such surgery, but that by co-operation in the work *we may help the men who are striving to advance surgery, and not themselves, to accomplish their end.* . . . It will make but little difference what I do perhaps, except it be that I may make it easier for other men to do the work that you and I would like to have done."

Like many men of positive natures, he created opposition to his projects, and of this opposition he was sometimes impatient, having a naturally high temper, which, however, he usually controlled with a masterful hand.

He won most of his victories by hard hitting power, great energy, a clear view of the goals he desired to reach, and by holding inflexibly to the paths that led to them, rather than by persuasive influence.

He was a most generous opponent and no one ever acknowledged his own mistakes with greater freedom or frankness. What he says in another letter bears testimony to the truth of this statement, as does a little episode to which, though personal, I may be permitted to refer afterward. In the letter he speaks as follows:

"I think I see the truth so clearly that I become impatient with some who differ with me. The heat of the discussion at the moment makes me forget the amenities. I know the defect and shall always fight against it. Thank heaven you are right in not attributing it to a dictatorial or arbitrary spirit, but the world so regards it. I hate that spirit heartily, but I give the world the impression of possessing it. . . . I shall keep your letter and read it from time to time. I thank you for its straightforward and friendly chiding which I need."

The personal incident which gives a glimpse of his open-mindedness occurred in the course of a discussion of a matter with regard to which we held opposite views. The argument became heated, and at length led to some very sharp words from me. His anger was thoroughly aroused, but he presently succeeded in controlling it, and, after a few moments' silence, he turned to me and said with a smile, "Well! I suppose we shall go on fighting to the end of the chapter, but, thank heaven! we are nevertheless good friends because of that," and with a hearty handshake he bade me good-night.

How disinterestedly he worked for the improvement of surgery, for the general welfare of his associates, and the efficiency of the institution is shown in his action with reference to establishing continuous service in the surgical wards of the Boston City Hospital. He became convinced of the desirability of this system early in his career, and when he had become a member of the senior staff he presented a plan by which he believed that the efficiency of the surgical work would be increased and by which his younger colleagues would be much benefited through having an earlier opportunity to do major surgery than was the case under the system then in vogue. It was also a plan which necessitated his own withdrawal from the position of Senior Visiting Surgeon which he then held and becoming again one of the junior grade, from which he had recently been promoted. The sacrifice was made greater by the fact that this would deprive him of the control of an independent clinic during his term of teaching in the Harvard Medical School and thus make it more difficult for him to demonstrate his ability as a teacher — an important loss, inasmuch as he was at the time a candidate for a surgical professorship in the school.

He strove to secure the acceptance of this plan which was to his own disadvantage with as much zeal as most men display in seeking

ends by which they will personally profit, and finally succeeded in having it adopted. This was but one of many public-spirited acts that marked his progress in the profession.

As an organizer and administrator he showed conspicuous power. Few men in our profession have these qualities or seek to develop them, and in consequence of this fact he had a large share of such tasks thrust upon him. He executed them strikingly well and thereby placed the profession not of this town alone but of the whole country much in his debt. Of the qualities that contribute to make the successful organizer he had in marked degree those of being able to select the man best suited to carry out each detailed part of the work and of not interfering with his subordinates once he had placed the responsibility in their hands and was satisfied that they understood the nature of it.

He was essentially a constructive worker and never sought to tear down what other men had reared until he was convinced that he could put something better in its place.

He compelled the admiration of all who stood near enough to him to know how broad his aims were and how high the motives by which he was guided while seeking their fulfillment.

A friend who knew and who loved him well put into words to me not long since the dominant note of his life and character in saying that "*he had a passion for service.*"

What that service was may be measured by the lack felt in many important places now deprived of the support of his firm hand, strong will and public spirit. Time only serves to make more clear the bigness of this man and has brought to many who had not fully recognized it while he lived the realization of how greatly he strove for the good of others and of the enterprises to which he was bound, how little he considered himself and how high was his purpose.

DR. GEORGE H. MONKS: I well remember that on one occasion when Dr. Burrell and I were talking about the education of children, he said to me something like this: "I don't know how far I can influence the development of my boys' characters, but I *do know* that I shall try in every way to impress them with the importance of having the highest ideals, and of working towards them."

As I think over Dr. Burrell's career I feel more and more convinced that in his own case the honest pursuit of high ideals amounted almost to a passion with him; and that it was this characteristic, aided, of course, by his superb courage, his loyal devotion to a cause and his persistent and well-directed effort which enabled him to accomplish all that he did in his fifty-four years of life. When once convinced that a certain thing ought to be done, and that he was the person to do it, he never hesitated, but, after thinking out all the essential details with the greatest care, he plunged into the midst of the work, full of energy and interest, and continued in that work, never thinking of his own personal sacrifices, of the loss of time or of the trouble he was giving himself, until all the obstacles were overcome and the task was accomplished.

I have known him over and over again give up opportunities which offered the prospect of large financial returns to attend to matters which for him had no return whatever except the satisfaction of work well done.

Although the principal achievements of his life are familiar to us, it might be well to see what a list they make if we put them together.

Not only did he pass through the various grades in the surgical departments of the Boston City Hospital, the Children's Hospital, the Carney Hospital and the Harvard Medical School, reaching finally in each of them the highest position, but, as we all know, his record of accomplishment in other field of work was in a way even more brilliant.

In 1893 he was appointed by Governor Greenhalge surgeon-general of the state, and the reforms he instituted and the innovations he introduced while in this position resulted in a system so remarkable as to excite the admiration of all who knew of it and to lead to its being adopted by other states.

He was secretary of the American Surgical Association (1895–1901) and all the older men of that association well remember the powerful uplift that he gave to that organization when he was in office.

If I mistake not, the original idea of fitting up the hospital ship *Bay State* during the Spanish War emanated from Dr. Burrell's fertile brain. How well he succeeded in awakening the public interest in that great undertaking, and how much of his time and strength were given in bringing it to fruition, we all know. It was no surprise to any one when Dr. Burrell was placed in charge; he was obviously the one man for the place. We also know about his three trips to Cuba and Porto Rico; in fact, his relief work in the *Bay State* has been called "his most notable achievement." All these things are now matters of history.

The *Journal of the American Medical Association*, referring to the meeting of the association in Boston in 1906, said, "The success in every detail, the harmony among vast numbers and the elaborate preparedness for the meeting were subjects of remark by all who attended the Boston session." Without question, the great success of this meeting was due to Dr. Burrell more than to any one person.

And, finally, he became president of the American Medical Association. Soon after this there appeared in the Association's journal of June 15, 1907, an editorial under the heading "The President Elect." It began as follows:

"The sturdy fidelity of New England to the best interests of the profession and its manifold contributions to the science of medicine and surgery are fittingly recognized in the election of one of its brilliant sons to the presidency of the American Medical Association. True to heredity and tradition, the sons of New England

have not hesitated to be pioneers in medical fields, and many a new trail has been blazed by them. They have always been ready to give their best effort and to make sacrifices for the realization of ideals, for the elevation of standards and for the equalisation of privileges. Any fit representative of such a noble section of our country must stand high in ideals, ability and attainments. Such a man is Herbert Leslie Burrell, president-elect of the American Medical Association. Imbued with high ideals for the usefulness of the profession to the public, of notable ability tested in many a trying situation and with a magnificent record of achievements behind him, Dr. Burrell well represents his part of the United States, and his position will emphasize to the New England men their recognized part in shaping the medical affairs of this nation."

As president of the Association his course was such as to reflect further credit and honor not only upon himself, but also upon the section of the country from which he came.

Still later he became president of the Massachusetts Branch of the American Red Cross Society, a position which he held up to the time of his death last April.

As a surgeon, especially in his earlier years, Dr. Burrell did a great deal of excellent and original work, and the articles which he wrote were of a high order. I well remember his oration before The Massachusetts Medical Society on the out-of-door treatment of tuberculosis, in which he urged, and I think he was the first to do so, that this treatment was as applicable for surgical as for medical cases.

As a teacher of surgery and as an organizer of the teaching department, — and this work stood very close to his heart, — he was admirable. His long and faithful service in these directions is so well known as to call for no further comment.

I cannot, as one of the surgical staff of the Boston City Hospital, let this opportunity pass without a word of acknowledgment, on my part at least, of the very large debt which we owe to Dr. Burrell for what he has done for that institution. I do not hesitate to say that most of the great improvements on the surgical side of the hospital which have been made during the last twenty years were brought about as a result of Dr. Burrell's initiative, and of his hard and devoted labor in carrying his ideas into effect.

In speaking or writing about Dr. Burrell, our thoughts are so fully taken up by a consideration of the work that he accomplished, that too little, I think, is said about him as a man.

In his relations with other men he was always straightforward, honest and generous. He took the greatest interest in the younger men, and often went out of his way and put himself to a great deal of trouble to help them out of their difficulties and to give them opportunities to work. His kindness and unselfishness in this respect were especially characteristic of him. To his friends he was ever devoted and loyal. Such few faults as he had, in view of his well-known sterling qualities and of his magnificent accomplishments, were not such as to leave any lasting impression.

Such is the man who is with us in memory to-night — a man of strong character, of unselfish devotion to high purposes, unfailing courage, sterling honesty, persistent industry; a man whose life was largely given up to the pursuit of the highest ideals, calculated to uplift the medical profession and to extend its usefulness.

His brilliant achievements reflect credit not only upon himself, but upon this entire section of the country.

His life and his works will long remain as a shining example of what can be done by devotion to lofty ideals combined with the courage, the intelligence and the hard work necessary to make these ideals effective.

## THE TIME AND METHOD FOR PROSTATECTOMY.*

BY BENJAMIN TENNEY, M.D.,

*Surgeon to the Boston Dispensary and the Berkeley Infirmary; Instructor in Surgery, Tufts Medical School.*

With all that has been written and demonstrated of the operation of prostatectomy and its results there is yet too large a part of the profession and the public who look back to the early days of surgery for their decision. Abdominal surgery has not offered safe treatment for much more than twenty years, and prostatectomy is a later operation to be put on the safe list. In 1906 Dr. Chase and I published a paper on the mortality from prostatectomy,[1] its fatal periods and its causes. Among other records we looked up the mortality in public hospitals from 1895 to 1905 and found it remarkably high. In one splendid institution one case in three had died, and in another one case in five. During that period thousands of house officers, students, dressers, nurses, ward men and members of the medical staff had seen a few of these cases and decided that the risk was too great to justify the operation on their patients and friends, and that impression still clings to them and influences their advice. It is with the hope of altering this impression among some of my medical friends that this paper is written.

There are three classes of men over forty who consult a physician for symptoms which may be due to prostatic obstruction. First, those with residual urine, without cystitis, whose complaint is of frequent urination, night urination, difficult urination or albuminuria. Second, those with residual urine and infected bladders. Third, those more or less dependent on a catheter.

With all these patients the same fact applies. It is not the hypertrophy of the prostate that makes the patient suffer; it is the obstruction. I have removed a nodule the size of the end of my thumb from a man who had passed no urine without a catheter for more than a year, and a huge prostate weighing 256 gm. from a man who had used a catheter but three times and had

* Read before the Malden Medical Society, Jan. 14, 1911.

[1] Jour. Am. Med. Asso., May 13, 1908.

but 2 oz. of residual urine. Both men were uncomfortable, and the man with the larger prostate was the more so, but the first had complete obstruction, while the man with the big prostate could still urinate and had but two or three night urines.

The number of men over forty who complain of frequent urination, night urination, difficult urination or albuminuria is very large and includes some who have no prostatic obstruction, but the important thing is that it *does* include all those who do have prostatic obstruction in the early stage. There must be many such now under treatment or neglect with a diagnosis of cystitis, pyelitis, pyelonephritis and even Bright's disease who are suffering from prostatic obstruction. A simple catheter is usually enough to settle the diagnosis. If the catheter will not go in with ease there may be some other form of obstruction which will keep the urine from flowing out, but if the catheter passes easily and residual urine is found, the diagnosis of prostatic obstruction is made.

Should we operate on these early cases? If we can relieve the obstruction by massage, sounds, dilators, the answer is, No. So long as a man can empty his bladder there is no good reason for removing an organ which may trouble him later but does not now. If the measures suggested are not successful, there is still opportunity for a difference of opinion. To me the fact that there is residual urine proves that the bladder is working harder than it was intended to, and the compensatory thickening of the bladder wall is a warning of a contracted bladder to come later. Operating through a thick bladder wall is less easy than through the normal, but that is a small matter beside the fact that a contracted bladder is exceedingly slow to resume normal capacity after a removal of the obstruction. The disappointing operative results are found among the patients whose bladders will hold but two or three ounces before they have been operated. They continue to have night urination and daily frequency for a long time after they leave our hands.

The comparative risk of operating on men with clean bladders and septic trabeculated bladders is to be considered as well as the chance of ascending and general infections. Personally I do not think the increasing age of the patient is of great consequence except as these progressive results of obstruction appear.

My youngest patient was forty-six, and I was able to sew up the bladder and send him home at the end of ten days with a tight bladder. I have not felt justified in trying it with my others, all of whom have been above sixty with one exception, but the contrast between the rapid convalescence of this patient and that of the patients with infected bladders was almost as great as that between patients with interval and drainage operations for appendix inflammations. I believe the time has come to advocate early operation, that is, operation as soon as prostatic obstruction can be demonstrated by the presence of constant residual urine, because there is present an anatomical condition which will by no possibility disappear and which will probably increase; because this condition will produce pathological changes in bladder, ureters and kidneys; because as a result of these changes general health will suffer, discomfort will increase and the period of usefulness be shortened; and because at this time the operation is less of a shock, practically without danger if properly done, and the convalescence is comfortable and short.

Recent statistics as to the frequency of malignant disease in hypertrophied prostates furnish another argument for early and complete removal.[1]

The second class of patients includes the majority of all who call for help. They have not begun to use a catheter and they are often ignorant of the condition which sends them to a physician. They are slowly going down hill, losing sleep, losing strength, growing old faster than their years warrant. Their urines are alkaline, contain a little albumen, often a few casts and white and red blood corpuscles. They rise two or more times at night to urinate and pass urine every two or three hours by day. Many of them think they have a "little kidney trouble" and have gone the rounds of physicians and proprietary remedies. It is unfortunately true that they can find a large number of physicians who will accept this ready-made diagnosis when confirmed by the albumen findings in the urine and who will try to work the miracle of curing them of a mechanical difficulty by pill and potion. For these patients we have but two alternatives; we can put them into the third class and let them use a catheter more or less frequently, or we can operate. There is no other alternative if they are to live with any comfort. The first alternative is often chosen from fear of death from the operation and sometimes from the knowledge of some one who has been operated and has incontinence or the need of using a catheter after the operation. For four years I have had the opportunity of watching the progress of such a case living under the most favorable conditions. He had a stone crushed and evacuated in 1901. Symptoms of obstruction appeared in 1904. In 1906 he had three ounces of residual urine, alkaline and cloudy. He rose every hour to urinate by night and was called to the same function every hour or hour and a half by day. After a few weeks of treatment his residual dropped to one ounce and his nights were disturbed but two or three times. Gradually the residual increased to four and five ounces and his night urines to three and four in spite of the best non-operative treatment that I could give him. He has been comfortable all the time except on one occasion when his plans were interrupted by another physician who was alarmed at the amount of pus in the urine and sent him home from a vacation trip. The case

[1] Cohn: Deut. med. Wochenschr., Berlin, April 1, 1909. Young: Ann. Surg., January, 1910.

has taught me much that can be done for the patients who utterly refuse to consider any operative procedure. I did not suppose they could be kept as comfortable for so long a time. On the other hand, this man is now seventy-nine and the chance he once had of a comfortable convalescence and a prompt recovery is growing more remote, and he requires the constant attendance of a nurse.

For a man who can have every comfort and care, the problem is different from the one whose care is fitful and not of the best. Such a patient is likely to suffer much and die within a year or two unless he can be taught to use a catheter cleanly and regularly or have unusual powers of resistance. One of my patients who had frequent attacks of cystitis in spite of much washing of hands and boiling of catheters used to mourn his hard luck when he had a neighbor who carried his catheter in his hat band and lubricated it with saliva with no unpleasant results.

Even the man who is most comfortably situated is better off with a bladder that empties itself than he can be with the most minute care possible.

One of my first patients had depended on a catheter for six years, during which time he had been operated for hemorrhoids and had perineal section for stone. After the enucleation he was two months in recovering perfect control of his sphincter, which had not been exercised during his catheter life. The change in his general condition and his delight in nights of undisturbed sleep were as striking as his regret that the prostatectomy was not done earlier.

I believe in operating on prostates with cystitis because the operation will cure the cystitis and guarantee against a return; because, with relief from the discomfort and opportunity to get their sleep, they will gain in general health and usefulness; and because it allows proper drainage of the ureter into a clean bladder instead of keeping its orifice submerged in a pool of purulent urine.

I do not see room for a difference of opinion about the desirability of operating on these cases. The danger and discomfort of the operation is less than the danger and discomfort of going without, and the successful removal of a benign hypertrophy promises absolute and permanent comfort so far as the bladder is concerned.

The third group will include all who use a catheter one or more times daily. If they are entirely comfortable using a catheter four or six times in twenty-four hours they may safely be allowed to continue if they prefer it, but they should have the option of the operation and freedom from such annoyance. Such cases are ideal for operation because of their proved resistance to infection, their toleration of urethral instruments, their normal bladder capacity and the probability of a definite, easily removed obstruction. Just as soon as the frequency of catheterization begins to increase there is proof of beginning infection, and unless a short course of antiseptic washing restores the normal intervals, operation should be prompt. They go from bad to worse more rapidly than any of the others here described, and the risk of the operation increases just as fast until a point is reached where the prostatectomy must be preceded by a long drainage period to be safe.

I believe in operating on both classes of catheter patients — those who are comfortable because of the slight risk and the guarantee against future trouble offered by the successful operation, and those with painful cystitis because there is nothing else to do to save life and comfort for their remaining days.

### THE METHOD.

Castration and the cautery knife are now historical. The literature of to-day refers only to the perineal and suprapubic operations.

Of the former there are two variations, the urethral and the transcapsular, and in operating by the suprapubic route some prefer removal in one or at most two portions, while others enucleate as happens to be most easy.

Anatomically almost all hypertrophies of the prostate are in part at least intravesical. This may be denied by some whose knowledge is limited to cystoscopic views and perineal operating, but I am positive of its truth from the cases I have operated, from autopsy specimens, from the lengthening of the urethra in most cases and from the fact that the mucous menbrane and internal sphincter of the bladder offer less resistance to upgrowth than is found in any other direction. There is probably no hypertrophied prostate which cannot be removed through a perineal incision, but no large one can be dragged out through the urethra without injury to ejaculatory ducts or sphincter unless in small pieces, and the same must be in less degree true of the transcapsular operation.

If twenty per cent of hypertrophied prostates are in some degree cancerous, the objection to morcellation is evident. If the wound be left entirely open, or a large tube be left from the bladder to the dressing, an ideal drainage is provided, but the importance of this may be overestimated. In gross, recovery from operations through the perineum has been a little better than from the suprapubic operation, but as Dr. Chase and I have before pointed out, there is a much greater difference in mortality reported among men doing the same operation than there is between the gross statistics of the two operations, and these gross statistics are coming nearer together each year. It is generally admitted that the late results of the suprapubic operation are more satisfactory.

The reported higher mortality of the suprapubic operation is really the only argument against its adoption as the general rule, with the perineal operation for occasional use. The preference of men already experienced, in other perineal operating, for perineal prostatectomy may partly account for a difference in results. Another explanation has occurred to me. The tables previously referred to show an admitted mortality due to "shock and hemorrhage" nearly three times as large in the suprapubic as in the perineal

results. Most of these cases really mean hemorrhage, and the source of the hemorrhage becomes important. It is mostly venous and the veins are most numerous where the hypertrophied prostate is in contact with the internal sphincter.

In urethral perineal prostatectomy the separation is downward, the finger is hooked over the top and the masses are dragged out. The same result is accomplished by the retractor and traction forceps in the transcapsular operation. In doing a suprapubic enucleation the natural movement is to use the same hooked finger before the prostate has been fully separated from its upper attachments all around. Doing this, one is likely to peel up a strip of the bladder wall itself and open into the rich plexus of veins. I have seen strips of mucous membrane and even portions of a seminal vesicle in the material removed by premature "hooking."

A suprapubic enucleation should be done with a straight finger until the hypertrophied gland is entirely separated from *all* its lateral attachments. I cannot help thinking that the enucleation downwards which is a feature of the perineal work has been one of the reasons for its better operative record, especially in the matter of "shock and hemorrhage."

I have had one death two days after operation on a cardiac case whose removed and remaining tissue showed extensive carcinoma, and no other mortality in the seven years Dr. Chase and I have been doing suprapubic prostatectomies. We have had no case of incontinence, injury to rectum or peritoneum. We have had one case showing infection of the prevesical space, five cases of epididymitis, and one patient who has developed cancer and resumed the use of his catheter four years after operation.

One case took forty-three days to close his suprapubic bladder wound, another twenty-seven days, and one was sewed up tight at time of operation. The rest have been tight in from fourteen to twenty-one days. The flexible metal catheter as perfected by Dr. Chase is an improvement over the gum elastic tube previously used, because it will not kink, rarely stops up, empties into a urinal without any extra piping, and gives all the "drainage" necessary.

We use no suprapubic tube and many of our patients keep their dressings practically dry after the first twenty-four hours.

The statistical difference in fatal results between the high and low methods of approach is steadily growing less. Either method well carried out if preceded and followed by minute and unsparing care will have a low mortality. Carelessness in technic or average after-care will send the mortality up with either operation. A prostatectomy is not a completed piece of work when the surgeon has washed his hands. The results of a perfect operation may be lost or a less perfect operation turned into a success by careful preparation of the patient for the ordeal and equally careful watch for and prompt action on danger signals after the operation.

I believe in the suprapubic prostatectomy because we are dealing with a tumor which is partially intravesical at least; because even the largest prostates can be removed entire or in two pieces without injury to rectum, sphincter or ejaculatory ducts; because recent studies of hypertrophied prostates show cancer formation to be comparatively frequent and morcellation, therefore, undesirable; because the slight excess of mortality does not seem necessary if enucleation be downward and the after-care correct; and because it has given results satisfactory to my patients and to me.

## SOME OF THE MEDICAL PROBLEMS OF ALCOHOLISM.*

BY IRWIN H. NEFF, M.D., FOXBOROUGH, MASS.

THE world-wide prominence given to the problems of drunkenness, the universal interest shown in the varied aspects of alcoholism, and the belief that the medical profession should take an active and leading part in a publicity campaign are my reasons for reintroducing a subject which to many may appear to have been worn threadbare.

From a sociological point of view the problems of drunkenness have received thorough and praiseworthy attention. It may be said that some of the viewpoints from a medical standpoint are lacking in scientific proof and have been too readily accepted. Thus it may be instanced that the relation of poverty to drunkenness, or the dependence of alcoholism on heredity, have never been accurately determined. These omissions have served to strengthen rather than to retard interest, and have not seemed to seriously handicap their work. They seem to have appreciated the magnitude of the task, and have gradually accumulated certain facts which have furnished them with admirable working capital.

My association with these people and with court officials has shown that they are anxiously awaiting more light on the medical aspects of the subject. They keenly appreciate that without the aid of the medical profession drunkenness must remain an unsolved problem. It would appear that they have no intention of usurping authority, but are forced by necessity to make the best of the material which they have on hand.

Drunkenness is a condition resulting from alcoholism, and inebriety is an expression of alcoholism. While the social and judicial problems would seem to outweigh the immediate medical considerations, I do not hesitate to say that the medical profession is expected to take a leading part in any plan which is inaugurated for the prevention or amelioration of inebriety. Physicians should accept this obligation and discharge it to the best of their ability; it rightly belongs to medicine, as it is first of all a remedial measure, and, secondly, educational along the lines of preventive medicine.

Judges, members of the courts and those interested in the care and cure of the inebriate have recently advised that a public campaign of edu-

* Read at the October, 1910, meeting of the Boston Society of Psychiatry and Neurology.

cation be inaugurated. Such a campaign has already been suggested for this state.

Physicians have championed the war against tuberculosis, and as a result they have not only added to their store of therapeutic knowledge, but have taught the public a lesson in economics. It has proven to the victim of tuberculosis that his disease is not incurable, and it has also taken away from the charlatan in part a means of livelihood. A glance at the advertised nostrums in our papers and periodicals will show that there is a perceptible and progressive decrease in the number of "consumption cures." This improvement is more evident if we contrast it with the numerous advertised cures for drunkenness. It would seem as if the quack, deprived of one source of revenue, had emphasized more strongly another phase of his character or versatility.

Apparently there is a general awakening of the medical profession to the realization of the need of concerted action to decide these problems, but to be successful we must proceed along definite lines and be absolutely sure of our premises. We have many problems to solve which require experimental, clinical and pathological research. A public educational campaign can only be successfully regulated by the medical profession. It would appear that such a campaign conducted on conservative lines would be of immense importance and of permanent value.

The study of a condition or a disease must necessarily begin by studying the environment or the individual responsible for the state or disturbance. Inebriety is no exception to this rule. The study of the inebriate must be the foundation stone for our medical analysis and for any suggestions for the control of drunkenness which we may make to the public.

It has always seemed to me that much of the misunderstanding about inebriety can be traced to our misconception of the word "inebriate." An inebriate is an habitual drinker. All cases of drunkenness are not cases of inebriety, but all confirmed or habitual drinkers are properly classed as inebriates. Inebriety has been called a disease; this has been vigorously opposed by those who would have us consider it a habit requiring only correctional measures for its control. The adherents of the habit theory have contended that the diseased conditions, whether mental or physical, are due to confirmed alcoholic indulgence. Again, it is maintained by some of those who are willing tentatively to consider inebriety as a disease that a general acceptance of this conception would serve to handicap any plan proposed for the suppression of drunkenness, as it might eventually lead to public belief that the inebriate is irresponsible. It is thus evident that the word "pathologic" as applied to inebriety should be used with caution and only after concise differentiation.

I have before contended that inebriety is a condition of nervous weakness on which is engrafted a habit. This conception of the conditions seems to me to qualify the assertion that inebriety is a disease. While calling it a "disease" we do not by accepting such a definition imply that the inebriate is irresponsible.

During the past two years we have studied the personality of our patients prior to the onset of the alcoholic syndrome, and while we are not as yet prepared to make a bald statement, we can say that in quite a considerable percentage of the cases a pathological nervous condition antedated the onset of the inebriety. When analyzing these nervous symptoms we have frequently encountered eccentricities, peculiarities, neuropathic and psychopathic conditions. In some cases distinct entities, as neurasthenia, hysteria and psychoses, could be differentiated. In other cases the conditions were more chaotic and did not admit of a differential diagnosis. It would, therefore, seem as if the word "pathologic" as applied to inebriety was admissable, but with our present state of knowledge its use should be restricted to those cases where the nervous or psychical conditions developed prior to the onset of the alcoholic syndrome.

There are some factors associated with the mental and physical condition of the chronic alcoholic or inebriate which are not generally understood. A reference to textbooks on psychiatry will give us a concise description of the mental and physical stigmata of alcoholism; the pathological findings are accurately described and it would seem as if the final word had been said. Recent studies in alcoholism and related diseases would seem to throw doubt on these textbook descriptions. It is quite necessary to make a sharp distinction between the effects of alcohol itself and the effects of certain other factors which also are usually present in the life of the alcoholic. There are very few diseases which are wholly due to alcohol; one of them is a form of peripheral neuritis, and, of course, chronic alcoholism is the sole cause of delirium tremens. "Alcohol is the chief cause of the common form of cirrhosis of the liver, and yet equally serious forms of cirrhosis of the liver are not the result of alcoholism. These three conditions are the diseases for which alcohol is chiefly and directly responsible. In the causation of many other diseases for which alcohol is commonly blamed, it does play an exceedingly important rôle, but this rôle is a hidden one." [1]

In our hospital practice we have recently encountered what appears to be a rather unusual form of alcoholic toxemia. Some of these cases have terminated fatally. The syndrome is an unusual one, and we have not as yet made a concise or satisfactory diagnosis. Some unsolved problems of alcoholism in addition to these mentioned are: First, the need of a more extended inquiry into the character and cause of delirium tremens; second, the exact relation of arteriosclerosis to alcoholism; thirdly, the frequency and character of organic physical disease in confirmed cases of alcoholism; and, fourthly, the exact relation of alcohol to insanity. These and many kindred subjects are before the medical profession for decision.

[1] Emerson, Charles P.: "Alcoholism and Disease." The Survey, Oct. 1, 1910.

A factor which is deserving of more than passing notice, and which is of extreme clinical value, is the general opinion that the inebriate is irreformable or does not lend himself readily to curative measures. The general belief is that an inebriate is untruthful, selfish and unwilling to assist in carrying out any plan which might lead to his betterment, and, moreover, this aggressiveness on his part is supposed to preclude any hope of permanent improvement. My experience would show that in many cases this is an exaggeration of facts. While it may be true that the irreclaimable inebriate, owing to loss of self-respect, is lacking in true insight, a considerable number of these cases are frank, appreciative and generally interested in measures put forward for their good. Their inability to carry out their good resolutions or to overcome their weakness must be considered as one of the expressions of their defectivity. It is a physiological fact that the most important result of alcoholism is a reduction in the vitality and resistance of the body. On the physical side this is shown by susceptibility to disease; on the mental side there is a decided loss in strength of the will. The individual study of the inebriate helps us to recognize many of our inconsistencies and is aiding us in correcting our errors. We must appreciate that the personality of the inebriate is an individual personality and cannot be expressed by a composite description.

There is no drug treatment of any value for inebriety. Drugs at their best are of secondary importance; it cannot be denied that a small number of inebriates have shown marked improvement after treatment by one of the so-called cures. I have personally investigated this phase of the subject and find that any improvement resulting from such treatment may be credited, first, to change of environment, and, second, to the memory of a natural disgust at the use of the drug employed. It may be said that this is a crude form of suggestive therapeutics and permissible if it improves a condition which is resistive to ordinary therapeutic measures. Such methods of treatment, however, should be condemned as they are unscientific and lacking in permanency of benefit. The methods of cure at the State Hospital in Massachusetts and hospitals for inebriates in this country and abroad are quite similar. We rely largely upon the building effects of pure air, good food, abstinence from alcohol or drugs, regular hours and out-of-door skilled labor, but this program is not in itself sufficient to cure the pathologic inebriate. The chief methods of cure of habitual inebriety, as in many other nervous affections, such as neurasthenia, etc., lie in arousing the patient's co-operation in his own recovery by educating the will. The inebriate, strengthened in body by a change of environment and out-of-door work, is also trained in mind to resist alcohol; his constructive interests are aroused, — if necessary, a skilled trade is taught; education is encouraged by libraries, lectures and discussions; the patient is prepared in both mind and will to meet and overcome the difficulties which he must necessarily re-encounter when he again leaves the hospital.

Those who are familiar with the types of inebriety have recognized that apart from the hopeful case there is a class of inebriates resistive to any curative measures. These can be properly termed custodial cases. Such cases comprise the "repeaters," and the prison population is made up largely of these defectives. Physicians in charge of the penal institutions of this state to which drunkards are sent assert that the large majority of habitual drunkards in their care are men of less than normal mentality. Whether this be cause or effect, it cannot be denied that the need of properly taking care of these persons is certainly as great as that of caring for the insane.

The advisability of committing inebriate patients to an institution has been questioned. It is claimed that institutional treatment is often a decided detriment. It is believed by those who oppose such treatment that institutions are harmful as they foster in the patient a feeling of dependence on the hospital and fail to develop in the patient a feeling of self-responsibility. To the question whether it is advisable to recommend institutional treatment for all cases, I would say that in the majority of cases the educational or re-educational measures, the basis of our treatment, can best be inaugurated at the hospital. The continuation of this treatment can be carried on away from the hospital under medical supervision and direction. It appears to me that no general rule can be given. In some cases it cannot be denied that hospital treatment without proper conditions would be detrimental to the interests of the patient.

In order to attain success in any plan which contemplates the relief to the inebriate it is imperative that there should be a keen and concise differentiation. Unless this is recognized, our purposes will often be defeated. Individual treatment is the only method of treatment which is of any avail. Those who fail to recognize that each inebriate is an individual case, each case requiring individual consideration, will often fail to benefit the patient.

I quote the following pertinent paragraph from a popular magazine article: "Rescue mission workers, priests and clergymen hold a record for genuine cures of alcoholism of which physicians may well be envious. They direct their attention to the man's person and spiritual life, paying particular attention to his environment. The will is alcohol's chief point of attack, and there must the main defense be made. The man realizes the need of a strength not his own, and with this he often wins."

I have purposely left until the last the most important question, namely, a consideration of the after-care for the patient. The following paragraph explanatory of our present methods is taken from the special report of the Board of Trustees of the Foxborough State Hospital submitted to the last General Court:

"Mere training of the patient is in itself an inadequate provision, when the man is forced to

return immediately upon discharge from the hospital to an unsanitary home, to evil associates, domestic troubles and casual labor. In Great Britain the Inebriates Reformation and After-Care Association has been formed to meet the inebriate when he leaves the hospital, and find him work and proper associates. The British association, however, is at a disadvantage in that its officers know nothing of the patient previous to his discharge from the hospital, and also are not equipped to continue the medical treatment of the patient, or even to win his confidence. At the Foxborough State Hospital an attempt has recently been made to improve upon the British mode of after-care by employing a physician, familiar with the methods of the hospital and acquainted with its patients at the hospital, to conduct this work. Through the out-patient physician the treatment of the patient is supplemented by instruction to the patient's family in the nature of the disease of inebriety and the methods of aiding its cure. Total abstinence is urged within the family. The patient is further linked with constructive social interests, — the church, sympathetic friends, temperance fraternities, and the like. The man is helped to secure employment through the employment agency of the hospital. Men who have been casual laborers before their treatment, and have been taught a skilled trade at the hospital, are placed by its officers at that trade. Most important, however, is the visit paid by the out-patient physician of the state hospital to the ex-patient, by means of which the treatment which was practiced at the hospital is continued. If the physician concludes that the patient has left prematurely, he is advised to return to the hospital; if he appears safe at his home, he is aided with frequent counsel and encouragement. Contact is also kept up through visits to the hospital by the patient. Reports are required both from the patient and from his family. In this manner the psychological treatment begun at the hospital is continued and supplemented by the sociological measures of the out-patient physician, and the patient, trained in strength of will in the hospital, is equipped with an environment favorable to the exercise of his strengthened volition."

The after-care department of the hospital as above outlined has been in successful operation during the past year. The results have been eminently satisfactory. Our confidence in this new departure of the hospital can best be expressed by declaring it our purpose to make its development an important part of our hospital work during the coming year. The Commonwealth of Massachusetts has obligated herself to carry out the recommendations incorporated in the special report before mentioned. An abstract of these recommendations is as follows: The immediate purchase by the commonwealth of a large tract of land for the establishment under uniform medical supervision of a new hospital for men, a women's hospital and the gradual development of a detention farm colony. The hospital for men to receive: First, patients who come voluntarily or who are committed by the courts; second, young habitual drunkards placed on probation by the court on condition that they spend a specified period at the hospital; third, suitable cases which may have been transferred on parole from the detention colony. The hospital for women to receive: First, patients who come voluntarily or who are committed upon application; second, cases placed on probation by the court on condition that they spend a specified period at the hospital. The detention colony to receive non-criminal habitual drunkards from the criminal courts on indeterminate sentence.

It seems unnecessary for me to say that the inauguration of such a plan and its complete success depends largely upon the co-operation of the medical profession with state officials.

## Clinical Department.

### CASE OF FOREIGN BODY IN THE TRACHEA. STATUS LYMPHATICUS. DEATH. AUTOPSY.*

BY J. PAYSON CLARK, M.D.,
*Physician for Diseases of the Throat, Massachusetts General Hospital; Instructor in Laryngology, Harvard Medical School;*
AND
OSCAR RICHARDSON, M.D.,
*Assistant Pathologist, Massachusetts General Hospital.*

THE patient, a white boy aged sixteen months, inhaled a hulled peanut kernel on Sunday afternoon, Aug. 21, 1910. His parents, who lived in a town in Connecticut, said that they had taken him to several hospitals, but could get nothing done for his relief. They brought him to the Massachusetts General Hospital on Tuesday evening, Aug. 23, two days after the accident. I saw him that evening. The temperature was 100½ (rectal), pulse 158, respiration 40. His mother said he had eaten nothing since the accident, and, having traveled a long distance, he was much exhausted. During the physical examination he lay listless and apparently indifferent to his surroundings, although one could not say he was unconscious. Two radiographs were taken, which gave no indication of the foreign body or of the enlarged thymus. Although the respiration was rapid and noisy there seemed to be little if any obstruction to the entrance of air into the lungs, and there was no cyanosis. In view of the exhaustion and of absence of any indication of the necessity for immediate interference, it was deemed best to wait until morning, when the external conditions would be more favorable for operative interference. The patient had rather a restless night, but slept some with a narcotic. In the morning (Wednesday, Aug. 24) the rectal temperature was 100, pulse 140, respiration 30. There was the same semiconscious state as on the night before, the eyes more or less fixed, the eyelids half closed, the body relaxed. Ether was given very carefully and in small amount. The child was placed in the Rose position, and with a small Jackson tube spatula an excellent view obtained of the glottis. Something could be seen moving up and down the trachea on expiration and inspiration. The glottis was sprayed with a little 1% cocaine solution and a small pair of tube forceps introduced into the trachea then opened. As the patient expired, the forceps were closed. It was at once evident that they had closed on some-

* Read at a meeting of the New England Otological and Laryngological Society, Nov. 28, 1910.

thing which required considerable traction to pull through the glottis. When the forceps was removed the blades held nearly a whole peanut kernel, which separated into three or four pieces as it was released. The kernel had probably broken in the forceps, as it is most unlikely that if it had been in pieces in the trachea it should all have been removed with one grasp of the forceps. After the operation, which took hardly more than five minutes, the pulse at the wrist was almost imperceptible, the respirations were feeble and the patient looked badly, pale but not cyanotic. It was evident that the child was in very bad shape and that something must be done; so, at the suggestion of one of my colleagues that there might be still more particles of peanut in the air-passages, I performed tracheotomy. The child stopped breathing during the operation, which was rapidly completed. On inserting the tube another small piece of peanut was expelled. Artificial respiration started the breathing again. An enema of warm salt solution with brandy and a hypodermic of strychnia were given and hot water bottles were put in the bed. He now breathed in a peculiar

Thymus. Status Lymphaticus. Massachusetts General Hospital. a. Right border of enlarged thymus. b. Left border. c. Lower border. Photograph by L. S. Brown.

manner, deep inspirations alternating with periods when the respirations seemed to have ceased. There was no obstruction to respiration. The pulse at the wrist was very faint and rapid. While we were watching him, he suddenly had a violent convulsion, clenching of the fists, flexion of the hands at the wrists, opisthotonos and twitching of the muscles of the face. This seizure lasted not more than a minute. As soon as it was over he was taken to the ward. He had not been there more than twenty minutes when the nurse reported that he was dead. I went at once to the ward and found that this was the case, also that, although the body was still warm, rigor mortis was already present.

AUTOPSY.

The permission of the parents having been obtained, an autopsy was made by Dr. Richardson on Aug. 25, eighteen and one-quarter hours post-mortem.

*Anatomical diagnosis.* — (A portion of a peanut was successfully removed from the trachea in this case, but was followed shortly by death.) Tracheotomy wound. Status lymphaticus. Meckel's diverticulum.

A male child sixteen months of age, 82½ cm. long, very well-developed and nourished. Race: American. Head: Not examined. Trunk: The neck presents a tracheotomy wound in the usual situation. It is in good condition. On section subcutaneous fat in good amount; muscles not remarkable; peritoneal cavity free from fluid; peritoneum smooth and shining; appendix not remarkable. The anterior margin of the right lobe of the liver is one finger breadth below the costal border in the right mammary line. Diaphragm, right side, fourth interspace; left side, fifth rib. Pleural cavities free from fluid. Lungs free. The thymus gland is present and greatly enlarged. It is roughly in the shape of a much flattened pyramid and reaches from a point a little below the lower border of the operation wound in the trachea down over the heart to the diaphragm. It measures 11½ cm. in greatest length by 6 cm. in greatest width by 2 cm. in greatest thickness. The broadest portion of the gland rests over the heart. The narrowest and thickest portion rests over the trachea. The gland is rather firm and meaty and its lower peripheral portions thin out to an edge. As the specimen is preserved, the weight cannot be taken. The bronchial and tracheal lymph glands show some enlargement, but otherwise are not remarkable. The trachea and bronchi are free. The lungs are not remarkable. Pericardium not remarkable. Heart weighs 53 gm. On section the cavities of the right side are engorged with blood and there is a rather considerable amount in the cavities of the left side. The organ otherwise is not remarkable, except that it is rather large. Aorta and its great branches and the venæ cavæ not remarkable. Liver weighs 351 gm. Not remarkable. Gall bladder, no stones. Bile ducts free. Pancreas not remarkable; duct of Wirsung free. Spleen weighs 40 gm. On section the tissue is firm, dark red in color, with very prominent follicles. Adrenals: Not remarkable. Kidneys: Combined weight, 74 gm. Capsules strip, leaving smooth surfaces. On section the tissue is of good consistence, the markings are retained and the cortex measures 4 mm. The section surfaces are rather pale; pelves not remarkable. Ureters free. Bladder, prostate and testes are not remarkable. Esophagus and stomach are not remarkable. The small intestine on section shows very prominent Pyers patches and follicles with some reddening of these in places. The lower part of the ileum presents a typical Meckel's diverticulum about 5 cm. long and of the same caliber as the intestines. The lumen of the diverticulum communicates freely with that of the ileum, and the mucosa is not remarkable. The large intestine on section shows prominent follicles with some reddening of them in places. The mesenteric and retroperitoneal lymph glands are more or less enlarged and pale. On section the tissue is not remarkable. The larger glands measure at least 2 cm. in greatest dimension. Bacteriological report: Culture on blood serum. Spleen. No growth.

In the analysis of this case interesting questions arise upon which one may speculate with possibly some profit even if no definite answers can be arrived at. Would it have been possible to diagnosticate this case *intra vitam?* Let us see what were the features present which are characteristic of status lymphaticus. Plumpness and a general rotundity of the limbs, a characteristic of these cases, was present, alone a very inadequate basis for diagnosis. There was no noticeable enlargement of the external lymphatic glands.

If the tonsils had been much enlarged they would have probably been noticed on passing the tube spatula, but no special note was made of the condition of the tonsils. The noisy respiration made percussion and auscultation very difficult and unsatisfactory, but even had it been otherwise, the site of the enlarged thymus over the heart and great vessels would have masked the greater part if not all the dullness caused by its enlargement. The same difficulty applies to the interpretation of the radiograph. The foreign body moving up and down in the trachea with respiration, if anything, only increased the shadow normally caused by the trachea. No one who saw the plates suggested that the shadow caused by the heart and great vessels was any larger than it should have been. Looking back at the case, the state of shock which was present when the patient was brought to the hospital was greater than one would expect after such an accident, merely from the irritation of a foreign body in the trachea and with little or no obstruction to the passage of air into the lungs. But this condition was attributed at the time to the excitement and exhaustion of the period following the accident. Dr. G. H. Cocks, in an article in the *Laryngoscope* for July, 1910, entitled "Status Thymo-Lymphaticus and its Relation to Sudden Death," says: "A finding of a lymphocytosis or diminution in the hemoglobin in the blood would aid in the diagnosis." But this diagnostic sign is of no value unless a blood examination is made a routine procedure before operation, which has not heretofore been our custom or been thought of as essential. If the diagnosis had been made before the operation, could any other possible method of procedure have prevented the fatal issue? It was quite evident that the patient's condition would not improve while the foreign body remained in the trachea. Its removal might have been attempted under local anesthesia, although this procedure is not free from danger in status lymphaticus. Dr. Cocks finds records of three fatal cases after local anesthesia. It should be remembered that under local anesthesia in this case we should have had the mental shock to the semiconscious child of the manipulation and instrumentation necessary for the removal of the foreign body. I question very much if the outcome would have been different. There was no evidence in this case of any mechanical compression of the trachea by the enlarged thymus. Death was apparently due to hyperthymization. In other words, death was due to a toxemia affecting the nerve centers and not to a mechanical obstruction to respiration although the mechanical effect on the heart of the enlarged thymus spread over it should be thought of as exerting a possible delaterious influence.

Increase of Cancer in Ontario. — During the seven years up to and including 1908, 8,769 persons of all ages died in Ontario from various forms of cancer. In 1902 the number was 1,048; 1903, 1,156; 1904, 1,253; 1905, 1,224; 1906, 1,411; 1907, 1,329, and 1908, 1,348. — *Jour. Am. Med. Asso.*

## REPORT OF THREE RECENT CASES OF BRONCHOSCOPY FOR FOREIGN BODIES.*

BY D. CROSBY GREENE, JR., M.D.,

*Surgeon to the Throat Department, Boston Children's Hospital; Assistant Physician to Out-Patients with Diseases of the Throat, Massachusetts General Hospital.*

The first case, a boy two and one-quarter years of age, was admitted to the Children's Hospital, in the service of Dr. J. L. Morse, Feb. 18, 1910. Four days before, while eating dried figs, he suddenly began to cough and choke. The following morning he coughed up a piece of fig, and the next day began to be feverish. Spells of coughing and choking continued at intervals. Physical examination made at the time of admission showed evident dyspnea; the left side of the chest moved less than the right in respiration; the breath sounds were diminished in intensity on the left side and entirely absent in the left back between the mid-axillary line and the left edge of the scapula. There was no dullness on percussion of the left chest. Auscultation and percussion of the right chest showed normal breathing throughout. The temperature was 103°, and the pulse 140 and the respirations 54. The history and the physical signs pointed to obstruction of the left bronchus by a piece of fig. An x-ray examination by Dr. A. W. George on the morning after the child's entrance to the hospital did not show any foreign body. Dr. Morse then referred the case to me for bronchoscopic examination.

The child was etherized and I introduced the smallest sized bronchoscope we had through the larynx into the trachea to the bifurcation. The right primary bronchus was clear, but the left was plainly obstructed. The mucous membrane was much reddened and swollen and the lumen thus narrowed was closed by a whitish plug. I was unable to introduce the bronchoscope into the bronchus and after a few ineffectual attempts to clear the bronchus with forceps I desisted for the time, hoping that my manipulations might have loosened the foreign body in its macerated condition sufficiently to enable the child to cough it out.

The child made a good recovery from the etherization, but the signs in the chest remained essentially the same. Evidently no air was going into the left lung. After a week, during which the child had a typical septic temperature, I made a second bronchoscopic examination. The appearance of the left bronchus was the same as at the first examination. This time I introduced a blunt hook into the bronchus a short distance beyond the apparent point of obstruction and withdrew it after making a slight turn. There was a little resistance to the withdrawal of the hook, but no foreign body could be made out and the bleeding which followed obscured the field of vision. Palpation and auscultation of the chest at this time showed that air was now freely entering the left lung. The child again made a good recovery from the ether, but his general condition did not improve, but grew steadily worse. A double purulent otitis media requiring paracentesis of both drumheads followed, and later definite signs of an abscess of the left lung. This was opened and drained through the chest walls by Dr. J. S. Stone, but the child survived the operation for only four days. Autopsy was not allowed.

It may be inferred, I think, that at the time of the second bronchoscopy the fig had become considerably macerated and was broken up and scattered into the lower bronchi by the manipulations. Whether the latter had anything to do

* Read at a meeting of the New England Otological and Laryngological Society, Nov. 28, 1910.

with the formation of the abscess is questionable. It is certain that conditions favorable to abscess formation were present before bronchoscopy was done.

I was handicapped in the use of the bronchoscope in this case in two ways. In the first place, it was just too large to be introduced into the inflamed bronchus, having a diameter of about 8 mm. In the second place, it lacked a sufficient number of fenestra at its lower end, so that when introduced into the opening of the obstructed bronchus it shut off the passage of air through the other. No air could then enter either bronchus. To obviate these difficulties I have had a special small tube made for use in young children, 6½ mm. in diameter, provided with several fenestra near its lower end. This tube I had occasion to use a few months later at the Massachusetts General Hospital on the second case.

A child one and one-half years old had swallowed a pin one week before being admitted. The x-ray plate taken on the day of admission indicated its location in

Diagram of situation in Case II. In the attempt to extract the pin by upper bronchoscopy, the point of the pin was passed through one of the fenestræ and became fixed in the wall of the bronchus.

the left primary bronchus with the head down. On the following day, under ether anesthesia, I introduced the new tube into the left bronchus, located the pin and passed the bronchoscope over the point so that the latter projected a short distance into the tube. I then seized the pin with the forceps and withdrew it a short distance, perhaps one inch, but at that point met with an obstruction. Finding it impossible to pull the forceps and pin out by moderate traction, I released the pin, drew out the forceps and looked again into the tube. The head of the pin was probably over the light for the illumination was dim and I could not distinguish the pin. I then decided to give up trying to get the pin out by upper bronchoscopy and attempted to take out the bronchoscope, but the bronchoscope would not come out either. It was evident that the point of the pin had gone through one of the fenestra and penetrated the wall of the bronchus, thus securely fastening the bronchoscope. Various maneuvers to dislodge the pin were in vain until, at Dr. Mosher's suggestion, I tried revolving the tube. The situation was becoming desperate and, therefore, at the risk of severely lacerating the bronchus and neighboring vessels, I turned the tube around two or three times. The bronchoscope was released with a click and I withdrew it. I then opened the trachea and passed a short tube down to the pin, engaging its point as before in the opening of the tube. The child was in the Trendelenberg position and a slight cough was sufficient to expel the pin before I had a chance to take it out with forceps. This child had naturally a rather severe tracheitis and bronchitis following the operation, but made a good recovery and was discharged from the hospital in good condition on the tenth day.

The third case was one of bronchoscopy for diagnosis only. A girl eight years of age was sent into the Children's Hospital, service of Dr. Morse, Aug. 11, 1910. She had swallowed a dried butter bean two days before, and about six hours afterwards was seized with paroxysms of coughing, with dyspnea and cyanosis. The attending physician had recommended her for admission to the hospital with a diagnosis of probable foreign body in the air passages. After examining the case Dr. Morse made a diagnosis of right lobar pneumonia. The child was under observation in the ward for a week. At the end of this time Dr. Morse found no material change in the physical signs. There was dullness over the entire right base; the temperature was elevated and the respirations were increased. At intervals there were sharp paroxysmal attacks of cough, with some dyspnea. In view of the atypical course of the pneumonia and the fact that much less air was entering the right lung than the left, and in consideration of the somewhat doubtful history of foreign body, Dr. Morse advised bronchoscopy. On Aug. 17, one week after admission of the child, I performed bronchoscopy under ether. A very clear view was obtained of both primary bronchi, and the bronchoscope could be easily passed into both. No foreign body was present. The mucous membrane of the right bronchus was a little more reddened than the rest, and there was slightly more secretion of mucus on that side. The child, far from showing any ill-effects from the examination under ether, improved almost immediately. The paroxysms of cough ceased, the signs in the chest disappeared and she was discharged from the hospital five days later.

In conclusion, I wish to emphasize the following three points which seem to me to be demonstrated in reviewing these cases:

(1) In bronchoscopy for recovering a foreign body which plugs a bronchus, it is important to use a tube which is provided with many fenestra in its lower part.

(2) In bronchoscopy for recovering a long pointed object, such as a pin or a needle, the necessity for fenestra is not so great, and their presence may cause a dangerous complication to the operation.

(3) Bronchoscopy may be performed even in the presence of an acute inflammatory process in the lung without necessarily causing any ill effects.

## HEMORRHAGE AFTER TONSILLECTOMY.*

BY HARRY A. BARNES, M.D., BOSTON.

THE objection most frequently advanced by the advocates of tonsillotomy against tonsillectomy is the danger of hemorrhage following the more radical operation. While I by no means wish to assert that this danger does not exist, nor, indeed, to belittle in any way the chances of its occurrence, nevertheless, as there is in the minds of many men, particularly of the general practitioner, a certain misgiving in regard to this, I should like to add my testimony to that of others as to the comparative safety of the complete ablation of the tonsil.

I know that the amount of blood lost during a properly performed tonsillectomy is insignificant compared with the amount lost during the average tonsillotomy; and my experience leads me to believe that the chances of post-operative hemorrhage are at least no greater and probably not as great in the new as in the old operation. During the past two years, on the summer service at the Boston Dispensary, there have been performed four hundred tonsillectomies, done either by myself or by assistants directly under my supervision. In all these operations the technic was essentially the same. But one case of post-operative hemorrhage occurred, and this one case followed the use of a tonsil punch at the base, though the operator had the evidence of an intact capsule on the excised tonsil to assure him that its removal had been complete. The hemorrhage, which came from the surface on which the punch was used, was controlled by methods of which I shall speak later.

Whether or not a greater number of hemorrhages would have occurred in this series of cases if a different technic had been used, of course no one can say, but I am inclined to believe that, to a degree at least, the freedom from hemorrhage was due to the method employed in the operation.

Three places in the sinus tonsillaris are especially prone to bleed after tonsillectomy, viz., the anterior and posterior pillars at their lower halves and the base between the pillars. This latter place is perhaps the most usual bleeding point. I never have seen a serious hemorrhage occurring in the upper half of the tonsillar fossa. The reason for this is that the larger vessels from the surrounding tissues enter the tonsil in its lower segment. Obviously, if no sharp cutting instruments are used at these danger points, the chances of hemorrhage will be greatly reduced. The operation which I advocate avoids these absolutely, and is performed as follows:

The tonsil is grasped with a two-pronged tonsil forceps, the upper prongs entering the tonsil at the level of the floor of the supratonsillar fossa, and the lower prongs as near the base as possible. The prongs of this forceps are about a quarter of an inch apart, are long and slender, and instead of being bent at a right angle to the shaft form a slightly obtuse angle with it. They are easily forced deeply into the substance of the tonsil, where they engage the larger fibrous trabeculæ without macerating the more superficial friable tissue. Even in the adult tonsil these trabeculæ become much attenuated as they approach the surface, and there they offer little resistance to the pull of a tenaculum; deeper down they are much heavier and stronger. The security of the grip of the tenaculum is of the greatest importance, especially in those cases in which previous peritonsillitis has created a network of adhesions with the surrounding tissues. Under those circumstances the line of demarcation between the tonsil and the walls of the tonsillar fossa can at times only be discerned by moving the tonsil in various directions, and it is most embarrassing to find the tenaculum constantly pulling away during this procedure. This instrument seldom tears through even the soft tonsils of childhood.

The forceps inserted, the tonsil is pulled gently forward and inward, so that the plica is put upon the stretch and is backed up by the bulk of the tonsil. With a long, sharp pointed knife (a peritonsillar knife is excellent) an incision is made just outside the inner border of the plica from its base upward and backward to the point of juncture with the posterior pillar. (I use the word "plica" to designate both the plica triangularis and the plica supratonsillaris.) This incision is carried through the anterior fold of the plica only, and immediately the deep fibrous layer of the posterior fold is exposed. It opens up what may be regarded as a closed fibrous sac, the walls of which completely surround the tonsil except over its faucial surface, and the inner edge of which is the double fold of mucous membrane which forms the plica. The walls of this sac are but loosely adherent except at that point in the lower half where the larger vessels pass from the deep structures into the tonsil.

A blunt dissector is now introduced into the incision, and unless adhesions are present this space may be opened up easily and the whole upper and anterior part of the tonsil turned out of its bed in the sinus tonsillaris. Slight adhesions may be broken by a more vigorous use of the dissector, but if the adhesions are marked, it is better to divide them with a knife, as the too vigouous use of the dissector thoroughly bruises the tissues, and a very painful throat results. The posterior pillar is not touched.

The importance of a perfectly sharp knife in making the initial incision cannot be overaccentuated, for, if the knife edge be dull, all delicacy of touch is lost; the operator cuts too deeply in his efforts to cut at all, goes through both layers of the plica and into tonsillar substance and so gets outside of the peritonsillar sac, and a clean dissection of the tonsil becomes difficult if not impossible. This is the origin of many of the so-called adhesions of the tonsil.

The loop of a snare threaded with No. 7 wire is now slipped over the handle of the tenaculum and then pulled down to a size that the bulk of the tonsil will just about fill. No danger of

* Read at a meeting of the New England Otological and Laryngological Society, Nov. 28, 1910.

catching the uvula is then present. With gentle traction inward and forwards, the tonsil is pulled into the loop, the canula of the snare being above and thrust downward behind the tonsil as far as the dissection permits. The wire is then pulled as tight as may be, the patient's head thrown forward, and while the ether is applied for the other tonsil, the snare is slowly screwed home. This last step should be very deliberate as it is at this time that all the larger vessels of the tonsil are divided. I usually take from three to five minutes in affecting the separation.

The bleeding after this operation is almost always slight; often the sheet wrapped around the patient is unstained. Lest some believer in more radical surgery, who dissects out his tonsils, even to the base, with a sharp knife or scissors should maintain that the entire tonsil is not removed by this method, I will say that nothing is easier of proof than the success or failure of the operation according to this standard. If the removed tonsil shows an intact capsule, then the ablation has been complete; and in the vast majority of cases such an intact capsule may be demonstrated. Even when the lower part of the tonsil is missed, as it occasionally is, it is easily removed by a second application of the snare.

Concerning the posterior pillar: I never dissect it because I think the snare does this better than any other instrument can do it. I never have seen the integrity of the posterior pillar in the slightest degree affected by the wire.

Often after the removal of a tonsil by the snare, a small piece of tissue which looks like tonsillar tissue is seen at the base, even in cases in which we are sure that the whole tonsil has been removed. For a long time I was at a loss to know just what this tissue might be. The end of the lingual tonsil sometimes encroaches very closely upon the base of the faucial tonsil, and if hypertrophied may be mistaken for a part of the latter. But the tissue of which I speak lies higher up in the tonsillar fossa and is, I think, nothing but the fibrous tissue subjacent to the tonsil, which has been gathered up into a bunch by the action of the wire. It contains the larger tonsillar vessels, and it is to the endeavor to remove it with a punch that two of the post-operative hemorrhages I have had were due. It is a dangerous place to cut and should be let alone.

I do not claim for this operation an absolute freedom from the chances of post-operative hemorrhage, but I think it has a sound anatomical basis and reduces that chance to a minimum.

In dealing with post-operative tonsillar hemorrhage, three methods are available, short of tying the external carotid artery. Exigences requiring this later procedure must be extremely rare, for in the last two years, during which tonsillectomy has been the rule at the Massachusetts General Hospital, there has been no case in which it was even thought of. I will take up these methods in the order of their simplicity, and it is in that order that I think they should be tried in any given case.

*First*, simple pressure. The patient should be etherized in this as well as in the other two methods. It is useless to attempt to do anything without it if the bleeding is at all severe; the patient soon becomes panic stricken and is then unmanageable. The upright position with the head forward, so that the blood is not swallowed nor inhaled, but runs out of the mouth and into the ether cone, is essential. With the mouth gag in place, a curved sponge holder with a gauze sponge at the end of a size to fit snugly into the sinus tonsillaris is inserted between the pillars of the bleeding side and pressed strongly outward; at the same time counter-pressure with the fingers is applied just behind the angle of the jaw. The sponge on the inside may easily be grasped with the fingers on the outside, and thus a very effective compression is put upon all parts of the tissues of the tonsillar fossa. This pressure may be continued for from five to ten minutes. I have had two cases that were completely controlled in this way. If after ten minutes' pressure the bleeding is not stopped, no time should be lost in passing on to the second method.

*Second*, ligation of the bleeding point or points. I believe in most cases of bleeding after tonsillectomy, barring cases of hemophilia and provided that the tonsil has been completely removed and no undue injury has been done to the surrounding tissues, that the blood comes from some definite vessel or vessels and does not come from an oozing surface. I say this both because the surface of the tonsillar fossa is composed of a fibrous tissue which is not well supplied with capillaries, and because my own experience is in accord with this view. The case of bleeding mentioned above in the four hundred tonsillectomies at the Boston Dispensary and one case at the Massachusetts General Hospital were controlled by ligation of a single point. Both were at the base and in each instance a punch had been used at this point after the tonsil had been removed by the snare. Pressure should be applied as in the first method described, as in this way the exact bleeding point is more likely to be found. If this can be determined, it is grasped with an hemostat about one inch longer than the ordinary and with rather a heavy and broad end so that no great accuracy in its application is necessary, as quite a breadth of tissue is included in the bite. As it is extremely difficult to tie this off after the usual manner, a suture is passed through the tissue with a sharp aneurysm needle, first from above downward in front of the hemostat and then from below upward behind it, making a sort of purse string. The hemostat is then removed and the suture tied with little danger of tearing away.

*Third*, suturing of the faucial pillars. In cases in which neither of the above methods is successful, the faucial pillars may be sutured. I have never had a case requiring this, but it has proved very efficient, notably in the hands of Dr. Crosby Greene. As I understand his method, the sutures pass completely around the tonsillar

fossa, so that when they are tied the fossa is obliterated and pressure brought to bear upon all parts of its surface. It would seem hardly possible that any hemorrhage should continue under these conditions. While I believe that many and perhaps most hemorrhages after tonsillectomy may be stopped by pressure or by direct suture through a limited area, it is, nevertheless, a comfort to know that such an efficient method of controlling the hemorrhage is at our disposal.

Shortly after writing the above, I had occasion to suture the pillars in a case of hemorrhage after tonsillotomy, seen in consultation with Dr. J. E. Somers of Cambridge. The patient, a child of six years, was undoubtedly hemophilic, though this was unknown at the time of operation. The bleeding, at first profuse, had somewhat subsided when I arrived half an hour after the start. It was, however, still free. Upon clearing the fauces of blood-clot the hemorrhage increased to such an extent that it was impossible to see any of the landmarks of the throat. As pressure with a gauze sponge had no effect, I immediately clamped with hemostats point after point at random in the tonsillar fossa. After six hemostats had been placed, the hemorrhage was sufficiently controlled to allow sutures to be passed accurately around the tonsillar fossa. Three silk sutures were placed; the hemostats were then removed and the sutures tied. They controlled the hemorrhage perfectly.

In placing these sutures through the pillars, I used an aneurism needle devised by Dr. H. P. Mosher for this purpose. The needle is passed around the tonsillar fossa and is then threaded by means of a slender suture-carrier with which the thread is easily and quickly inserted in the open eye of the needle. The needle is then withdrawn carrying the thread with it.

## Reports of Societies.

### NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.

A MEETING of the New England Otological and Laryngological Society was held in Boston, Nov. 28, 1910. Dr. A. C. Getchell, President.

DR. J. PAYSON CLARK reported:

#### A CASE OF FOREIGN BODY IN THE TRACHEA. STATUS LYMPHATICUS. DEATH. AUTOPSY.[1]

##### DISCUSSION.

DR. A. COOLIDGE: Whenever the larynx or the bronchi or the trachea is invaded by any instrument, there is always the possibility of respiratory shock. I have seen one or two cases myself which were quite striking. Is it not possible that this may have had something to do with Dr. Clark's case, the shock being due to the foreign body itself, or to the manipulation in getting it out? Status lymphaticus was primarily the cause of death, but may not respiratory shock have been a contributing cause?

DR. D. CROSBY GREENE, JR., read a paper entitled

[1] See JOURNAL, p. 115.

#### REPORT OF THREE RECENT CASES OF BRONCHOSCOPY FOR FOREIGN BODIES.[2]

##### DISCUSSION.

DR. A. COOLIDGE: The relative merits of lower and upper bronchoscopy depend upon the instruments at hand and the experience of the operator. If poorly equipped it may be better to do lower bronchoscopy, but under the proper conditions the passing of a bronchoscope through the larynx is an easy matter. I should like in this connection to report a case which came to the hospital a few days ago. This is the first time I think in this city that the use of the bronchoscope was substituted for an emergency tracheotomy. The patient came in on the surgical side with a tooth plate firmly impacted in the esophagus. The plate plate had been there nearly a week and was surrounded by edematous mucous membrane. After working down through the edema I could seize the plate, and in trying to unpin it from the sides of the esophagus I turned it half over, in which position it blocked the trachea from the esophageal side and I could not get it back again. The patient began to breath badly and became cyanotic.

It occurred to me to try to pass a bronchoscope. A small one was passed easily through the glottis, and then under direct inspection I managed to get by the obstruction. The patient immediately breathed well again. The esophagoscope was then again introduced, the bronchoscope being still in place, and an attempt made to break the tooth plate and to remove it in different ways. Not being successful, the patient was returned to the surgical side, and esophagotomy done by Dr. Greenough. The patient meanwhile breathed and was etherized through the bronchoscope. The plate was taken out by esophagotomy, after which the bronchoscope was withdrawn without farther trouble. The patient made a good recovery. This illustrates that occasions may arise of emergency when tracheotomy seems inevitable, in which it may be easier and quicker to pass a bronchoscope than to do a tracheotomy.

DR. A. C. GETCHELL: I think the question of removal of foreign bodies from the bronchi is a matter of peculiar interest to what we might call the provincial practitioners, and I count myself as one. That is, What is our duty in these matters? Dr. Coolidge says it is comparatively easy to pass a bronchoscope and get a good view, but unfortunately this procedure is one that cannot be done except with practice upon a living subject, and, therefore, the matter of acquiring skill depends upon the practical experience with the patient at hand. We of the outside do not like to pass by good things; we do not like to pass them on to the metropolitan practitioners, but the question arises as to what is our duty, and I have decided for myself, as most of these cases are cases which will admit of some delay, that it is not my duty and it is not wise for me to operate on them. But I think that those of us who do not have the larger advantages of the metropolitan hospitals should equip ourselves and have a fair degree of proficiency and readiness for the esophageal and laryngoscopic work.

I have seen in Worcester two cases of foreign bodies in the bronchus, and I am pretty sure I have seen all that have come to Worcester in twenty-five years. One of them was years ago before any direct bronchoscopy was done. It was a nail. After a period of apparent lung trouble, although it was evident what the cause was, it was coughed up.

The other came to me recently and I fancy it is the case that will be reported to-morrow. I think it

[2] See JOURNAL, p. 117.

must be the case, although I did not send my name in with it, yet the mother reported to me the result. This child was brought into the Memorial Hospital with the history of having swallowed a piece of candy and that the breathing had been labored since. The breathing was suggestive of laryngeal obstruction, but it was evident from the examination of the lung that there was obstruction on the right side, if I remember rightly. Now it was a piece of candy, the mother said, and the question was whether that candy would be dissolved. Then she said it was a piece of candy containing a peanut, and that decided me. I sent her here and I think the result was entirely favorable. There was no urgent necessity of doing anything at that time, and while it was not comfortable to one's feeling of pride to send this patient to another practitioner, yet I think it was the right thing to do and I shall do it in the future.

Are there any further remarks?

DR. GREENE: With reference to this matter of doing lower bronchoscopy through a tracheal opening in case any difficulty is encountered, I should qualify my statement by saying that this applies especially to infants and young children, like the case I had. A child of a year or a year and a half has a small bronchus and it is difficult to work on. I do not think you can work to the same advantage with upper bronchoscopy in these cases that you can with lower bronchoscopy.

The performance of tracheotomy immediately after or in the course of a bronchoscopy is not attended with as much danger and is not as difficult as the ordinary tracheotomy. The trachea is already cocainized and there is not that respiratory shock and the cessation of breathing that you get on opening the trachea under ether. It can be done more rapidly and easier under these circumstances than where the tracheotomy is done first before the trachea is cocainized.

DR. HARRY A. BARNES read a paper entitled

### HEMORRHAGE AFTER TONSILLECTOMY.[3]

#### DISCUSSION.

DR. D. CROSBY GREENE, JR.: I think the cosmetic effect of suturing the tonsillar pillars is not usually desirable and we do not do it for that effect. I do not think from my experience that there is any lasting damage to the function of the pillars in suturing them, even in cases where there has been quite a good deal of displacement and distortion of the faucial pillars, but I think if other means are efficient, it is best to try them first. It seems to me that the ideal way is to find the bleeding vessel, if we can, and ligate it. My experience has been that it is sometimes very difficult to find this vessel. I have seen cases where it could be seen pretty easily, but it is a more difficult procedure in general to find and ligate it than to draw the pillars together and suture them. I do not think there is any question of that.

I agree with Dr. Barnes in regard to giving ether for suturing or for tying. I have noticed that in a good many cases of hemorrhage after tonsillectomy the mere process of etherization seems to stop the hemorrhage, and it is of itself of great aid in controlling patients, especially children. If you have a patient under ether and the hemorrhage ceases, it does not necessarily mean it is all right; I am not confident that hemorrhage will not start after the patient comes out of the ether. Gagging and movement of the walls of the fossa will often make the patient bleed again, even if hemorrhage is stopped under etherization.

I have not always included all the underlying tissue. I think the essential point is to make a good bite in the pillars, not just suture their edges together. That is ineffectual.

## MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

### THIRTY-SIXTH ANNUAL MEETING HELD AT DETROIT, MICH., SEPT. 13, 14 AND 15, 1910.

(Continued from No. 3, p. 89.)

### GASTROSTOMY AS A CURATIVE MEASURE PER SE IN NON-MALIGNANT STRICTURES OF THE ESOPHAGUS.

DR. JOSEPH RILUS EASTMAN, of Indianapolis, Ind., stated the directly beneficial effects of gastrostomy in cases of so-called benign strictures of the esophagus were not generally appreciated. They had been too slow to break away from all notions which were developed in the pre-aseptic era when the performance of gastrostomy was attended with considerable danger. Ewald, in discussing a report of successful dilatation of a diphtheritic stricture of Rosenheim, referred to a peculiar observation which he had made in dealing with such benign stenoses, namely, the remarkable circumstances that cicatricial strictures for which gastrostomy had been made nearly always improved steadily after the stomach fistula had been provided and food had been introduced through the fistula instead of through the gullet, that is, the stricture gradually developed a larger caliber without any other treatment whatsoever. Ewald explained these phenomena in the following manner: After the gastrostomy was made it became possible to fill the stomach with food. The pull of the full stomach downward gradually stretched to some degree the elastic esophagus. When the stomach became empty the downward pull ceased, then the pressure of the food mass above the stricture had its effect upon the stretched and more yielding strictured segment. More compact masses of food might then squeeze through. The explanation of the phenomena given by Ewald could hardly be applied to all cases. After the swallowing of a hot or caustic fluid, the mucosa of the gullet might become deformed in many ways. Among many interesting deforming processes are, for example, the complete tube cast-like separation of the mucous membrane described by Strauss, the esophagitis dessicans superficialis of Rosenberg, and esophagitis exfoliativa. In these conditions, after the mucosa had become loosened from the underlying tissues and thrown into folds or ridges or pockets, it was easy to understand that the passage of food or of a bougie must be attended with great mechanical difficulty. It also seemed fair to believe that the downward traction due to the filled stomach must have the effect in some instances of smoothing the valve-like folds and irregularities of the loosened membrane, thus permitting the passage of food through a previously impassable esophageal lumen.

The gastrostomy was curative *per se* for another and more important reason. The rest afforded the esophagus was of the greatest value in allying the inflammation which preceded or attended practically all benign strictures. If ulceration be present, the passage of food, or what is worse, the arrest of food, with consequent fermentation, must maintain or increase the activity.

### FRACTURE-DISLOCATION OF THE ATLAS AND AXIS.

Dr. Carl E. Black, of Jacksonville, Ill., reported a case in which operative reduction was adopted. He called attention to the essential diagnostic points and gave some reasons why operative interference had not been adopted more frequently. He summarized the treatment of such injuries as follows: (1) Immediate reduction under an anesthetic. Walton had his patient sit in a chair while he turned the head still farther from the dislocated side. The head was then tilted to the sound side and extended while the column was rotated back into place. Hueter's method by rotation might be used. When the atlas was dislocated, before any method of reduction was undertaken, they should be sure that the odontoid process was not fractured. If the odontoid process was fractured, they were advised by some to follow the second indication and place the patient in a plaster cast which would immobilise the seat of injury until healing could take place, and then reduce the deformity. The objections to this plan are that it failed to give the patient any opportunity for relief before degeneration of the cord could take place, and subjected him to further pressure from callus, and finally it would usually be found impossible to effect reduction after so long a time. The third plan was operative interference. While considerations of the cord were all important in such injuries, they should not be deterred from making every reasonable effort to restore the dislocated or fractured spinal vertebræ, because many questions regarding the degeneration and regeneration of the cord were in the stage of controversy and remained unsettled. It would seem to be their plain duty to effect a restoration of the bony column as far as it could be done without further endangering the cord, except in those cases where the cord was hopelessly crushed beyond the possibility of the recovery of lost functions. The mechanical difficulties were great and often insurmountable, but perseverance with reasonable efforts to overcome them would certainly tell in time. It was a reasonable proposition that an injured cord had a better chance in a spinal canal with sufficient room than it had when held under even mild compression. For this reason the second indication should usually be omitted and the injured parts exposed thoroughly. If the case was one of dislocation, efforts at reduction could be repeated under the direction of the eye and finger, and failing in this a laminectomy could be made. This mistake of the treatment of the case reported was a failure to appreciate the compression produced by the posterior arch of the atlas.

### PREPARATION REQUIRED FOR THE PRACTICE OF GENERAL SURGERY.

Dr. G. W. Green, of Chicago, stated the public had a right to demand of the surgeon (1) a good foundation in the shape of a diploma from a good school. (2) Considerable time spent with a master of surgery, so that he had the following knowledge: (*a*) Sufficient experience to make a correct diagnosis. (*b*) Sufficient experience to know what it was best to do when a diagnosis was made. (*c*) That he should know just how to do the work and have enough practice to have a definite surgical technic of his own, so that he was capable of performing the operation he essays, or any complication which might arise from that operation, in an average length of time. (*d*) That his mortality should be as low and his post-operative results as good as those of the average surgeon. In return, the surgeon had a right to expect a fair remuneration and respect from the public, but no more than any other member with equal qualifications, specializing in any other branch of this, one of the noblest professions on the face of the earth.

### TUBERCULOSIS OF BONES AND JOINTS.

Dr. Edward M. Brown, of Chicago, read an exhaustive paper on this subject, and, among other things, said: The treatment of tubercular joint disease was (1) general or constitutional; (2) specific or serum treatment; (3) local. For practical purposes the local treatment might be divided into injection treatment, mechanical and operative. The advantages of operative treatment were: (1) The disease could at once be thoroughly eradicated, or so nearly so that the patient easily overcame the disease. (2) Dissemination of the disease was prevented. (3) The treatment was shortened. (4) The general condition of the patient rapidly improved. (5) The length of the limb and function of the joint were preserved to the best possible degree.

### THE RESPONSIBILITY OF PHYSICIANS IN THE TRAUMATIC NEUROSES.

Dr. H. H. Drysdale, of Cleveland, Ohio, in this paper discussed the history and manifestations of the traumatic neuroses in detail. In studying these conditions etiologically he had arrived at the conclusion that the true genesis, in a large majority of cases, was psychic, and that it was fright, fear of death, anticipated pain and anguish received unexpectedly by a totally unprepared sensorium which was the chief element to be considered. Psychologically fright was a fundamental emotion. Violent in action, it would under certain conditions of mind pervert the sense faculty, disturb the kinesthetic equipoise and deform the physical and psychical personality. He considered the manifestations of these conditions to be the involuntary expression of a break in the bodily feeling. These by degree tended to organize and combined to form a morbid mental state, a delusive conception, as it were, towards which every thought converged. A faulty environment frequently did more harm than the actual injury, as it tended to make the individual introspective and depressed, and as a consequence he threw aside the normal weapons of defense and surrendered himself to the misfortune which had assailed him. From an experience of 108 cases investigated from the standpoint of the corporation as well as that of the patient, and which included in many instances the pre-litigation, also the post-litigation, period, he had made several observations which he believed, if put into practice, would place the responsibility of adjusting these trying conditions on a scientific basis, and thus obliterate much of the confusion and disquietude which surrounded the traumatic functional disorders of the nervous system.

### HYGROMA OF THE TESTICLE.

Dr. Charles M. Harpster, of Toledo, Ohio, in his paper stated a hygroma was essentially a serous cyst, The bacillus of tuberculosis was often found, and the hygroma, if a true one, always contained hard caseous masses and rice bodies. A true hygroma of the testicle and cord was rare. The case he related was a man, forty-five years of age, who, for a number of years, suffered from a hydrocele, and this was frequently tapped by his family physician. Some months ago it was tapped and considerable blood and some pus were withdrawn. This alarmed the patient, and in consultation with the attending physician he found the testicle considerably enlarged and very painful, with some slight general disturbance. The cord and testicle were removed. Tubercle bacilli were found in the rice bodies

and tissue of the sac. Syphilis undoubtedly had been contracted but denied by the patient.

DR. RICHARD DEWEY, of Wauwatosa, Wis., reported a case of manic-depressive insanity with satyriasis, which was complicated by an abscess of the appendix. The starvation treatment was resorted to, followed by evacuation of the abscess and recovery.

DR. FRANK SMITHIES, of Ann Arbor, Mich., discussed some of the newer methods for the detection of tubercle bacilli, with particular reference to the so-called antiformin method.

### THE TUBERCLE BACILLUS CULTIVATED FROM CASES OF PRIMARY TUBERCULOUS CERVICAL ADENITIS.

DR. WILLIAM LITTERER, of Nashville, Tenn., in his paper stated nine consecutive cases of primary tuberculous cervical adenitis were examined, which resulted in the isolation of five cultures of bacillus tuberculosis of the typus humanus, and the four cultures of the typus bovinus, the classification of the types being made on the same basis of four tests, to wit: First, the morphological characters of the bacilli; second, the dysgenetic or eugenetic character of the cultures; third, the relative virulence towards rabbits, and, fourth, the reaction curve in five per cent glycerin bouillon. This latter test served admirably to distinguish between the two types, provided there was repeated application and careful control over a period, in some instances, of eighteen months. He had found that the differences in the growth of the two types dysgenetic and eugenetic on Dorcet's egg medium to be very valuable in differentiating the bovine from the human type of bacillus. Rabbit virulence had probably been more uniformly satisfactory than any of the tests in determining the differences between the two types of bacilli.

### THE TEACHING OF CLINICAL PSYCHIATRY; A MEDICAL EDUCATIONAL PROBLEM.

The President, DR. FRANK P. NORBURY, of Hospital, Ill., said the subject of the address was chosen as a text in order to present certain imperative demands of medical education of to-day. What was sought was to utilize the opportunities at hand, develop new ones, create higher ideals, readjusting ethical educational standards. The fundamental fact of the present controversy regarding medical education was that it was a part of the educational propaganda of the century — a world movement. In this country, guided in constructive analysis in medical education by the Council on Medical Education of the American Medical Association, this progress was based, first, on the integration of the educational system; second, the standardising of undergraduate work; third, the standardizing of professional courses in medicine. A virile contributory constructive power was the report of the Carnegie Foundation for the advancement of teaching, which had sounded a war-cry for medical culture, refinement in standards, appeal for higher ideals. Law standards gave medical education a commercial basis, and it became a common commodity. Modern medical education was in the transitory stage in teaching clinical medicine. This transition began with Osler's work at Johns Hopkins when he demonstrated that "teaching hath her victories no less than research." Clinical medicine to-day included the interpreters as well as the research workers. Medical sociology was the enlarged appreciation of the value of clinical medicine extended to the problems of etiology, preventive medicine, occupational diseases, and general and special civic problems. The scope and value of such work was unappreciated by the unthinking masses of the profession. Clinical psychiatry was prominent in this field of newer clinical activity. It was in contact with more points in life, its realities, its ignorance, its prejudices, its ethical discordance, and falsifications than any department of medicine. A real need existed to-day for the teaching of these master problems of the age. The teacher must be a biologist in its widest clinical interpretation; a sociologist, that he might grasp all etiological factors, and an internist, that he might be in touch with all of the physical factors entering into the problem. Modern medical teaching must give to the student the opportunity to see the whole at near range. The teaching of psychiatry was a state need, just as much as any other problem of preventive medicine.

### DIAGNOSIS OF SURGICAL LESIONS OF THE KIDNEY WITH ESPECIAL REFERENCE TO THE VALUE OF THE X-RAY AND THE CYSTOSCOPE.

DR. LOUIS FRANK, of Louisville, Ky., delivered the address in surgery. He said: Although the diagnosis of the character of new growths in the kidney might be impossible before operation, the recognition of a surgical lesion and of the surgical indications were not, as a rule, attended with great difficulty, provided a thorough, painstaking and complete examination of the individual was made. In renal calculus they had at hand means for physical examination which, in the presence of even very obscure physical symptoms, would render the diagnosis in most all cases practically certain. These were the cystoscope and the radiograph. The cystoscopic examination frequently showed a swollen ureteral orifice. The passage of the ureteral catheter would at once reveal from which kidney the blood or pus in the urine was coming. The cystoscope was not nearly so valuable an aid as the roentgen ray. It did reveal whether or not one kidney alone was involved, or whether or not a kidney had ceased to functionate. Although secondary in value in the diagnosis of renal calculus to the x-ray and to the clinical history, the cystoscope should always be employed previous to operation as an aid in ascertaining which was the diseased kidney and the condition of the other kidney in regard to the character and condition of its excretions. As a confirmatory diagnostic means the greatest value of the radiograph was in connection with renal calculi. The predominant signs of most renal affections of a surgical character were pain, hemorrhage, urinary disturbance and tumor. One or more might be absent or they might all be present in any given case.

### THE MODERN DOCTOR, HIS SUCCESSES, HIS FAILURES, HIS FUTURE.

DR. JOHN K. MITCHELL, of Philadelphia, delivered the address in medicine, and among other things, said: A time would come, since the disappearance of all disease was unlikely, when governments would make a more organized contest against it, would teach and enlist all physicians in a common army as they now educated and paid the soldier. This must come, because with improved sanitation and the constant advance of preventive means, illness would grow infrequent, so that unless he was a paid servant of the state the physician would not be able to exist. When that army was enlisted, the occurrence of preventable diseases would be as much a matter for court martial and the punishment of the person who allowed it to pass him as the failure in duty of a soldier asleep at his post. In that golden future in which sickness would be as rare as war is now, instead of being a single-handed fighter, the doctor would serve as an enlisted man in the great battle for life and strength against illness and pain; he would have no new duties, perhaps, but new powers, ability to enforce obedience

to laws of health, until, under wiser ways of life, death, the one unmedicinable disease, came only to the aged, approaching without notice, to be met without fear, bringing an ending peaceful and calm after an active life and a quiet old age.

MYOSITIS OSSIFICANS PROGRESSIVA.

Dr. Arthur R. Elliott, of Chicago, presented the clinical history of a case of this disease showing x-ray pictures, which clearly demonstrated the bony deposits in various muscular areas. The patient, a girl of seventeen, first displayed symptoms of the disease at the age of two. The involvement of the muscular system was widespread, resulting in many deformities and much restriction of movement. The general health had not as yet been greatly affected. Congenital malformations of the hands and feet existed, such as were observed in about 75% of recorded cases. This clinical record was the one hundred and second in the history of the disease since the first case was discovered by Fuke in the Philosophical Transactions in 1740. The etiology and pathology of the disease were briefly discussed.

NEUROLOGICAL AND PSYCHIATRIC ASPECT OF TUBERCULOSIS.

Dr. Charles H. Hughes, of St. Louis, Mo., stated too much attention had been devoted to the classical form of lesion of pulmonary tuberculosis and too little to the other conditions of the organism, especially to the state of the nervous system and what impression was made upon the patient's mind. He was dealing somewhat with the detrimental effect of adverse psychical suggestion, and he wished to enter a protest and be as emphatic as he could against the pronouncement positively, where it could be avoided, of a diagnosis of tuberculosis to the patient in its earlier stages, and the putting of the patient upon the outdoor treatment alone of tuberculosis. He entered his protest against ignoring the detrimental effects of psychical suggestion and would speak of the beneficial effects of it in the treatment of pulmonary and other forms of tuberculosis. To tell a patient, when he had his first hemorrhage, and the microscope revealed occasional tubercle bacilli, that he had tuberculosis and must sleep out of doors, or in a cold room, with his body well wrapped, or sleep with his face out of a window in all kinds of weather for the purpose of giving him fresh air, a thing to which he had never been accustomed, exerted a detrimental influence or adverse psychical suggestion and was a most potent influence in determining the fate of that individual. He had in mind a case that came under his observation. A friend of his was sent to Colorado at the time of his first hemorrhage. He was a vigorous man, but led a sedentary life. He neglected those physical influences that were necessary to rejuvenate the blood and increase its vital resistance, to build up the metabolism and improve the cytological processes. He went to Colorado under the psychic impression that he was affected with pulmonary tuberculosis, a sort of suggestion which sealed the fate of more patients than those who suffered from tuberculosis. He went there, occupied a cold room, and slept with his head out of a window, with a cage arrangement so as to screen himself against mosquitoes. He declined steadily. He is dead now, although he went there as a strong man physically. The adverse influence on that individual of psychical suggestion sealed his fate,— at least, prematurely. If the diagnosis and possible prognosis had been withheld in that case, in his opinion from what he knew now, the man might have been living to-day. The man who hastened to give a localised and fatal prognosis in a case did not thoroughly comprehend the influence of mind over organisms. He did not fully comprehend the influence of the higher psychic centers over the lower centers of metabolism, upward or downward. True therapeutics depended upon exalting the metabolisms of the organism and not in depressing them. Not enough attention was given from a psychotherapeutic standpoint, and from a neurotherapeutic point of view, to take care of the isolated nerve centers of the tuberculous patient, and in order to accomplish that, his digestion must be aided by continuous and unremitting hyperdigestion, artificially enforced, and an amount of sleep adequately secured.

*(To be continued.)*

## Book Reviews.

*Alcohol: A Dangerous and Unnecessary Medicine. How and Why. What Medical Writers Say.* By Mrs. Martha M. Allen. Published by the Department of Medical Temperance for the National Woman's Christian Temperance Union. Marcellus, N. Y. 1910.

This book, like many kindred publications, is a curious mixture of fact and fallacy. Despite its claim of originality, it is essentially a cento of quotations from medical writers of varying ability and reliability. It has been said that the devil can cite Scripture to serve his purpose. The purpose intended to be served by this volume is the exposition of the drug alcohol in such fashion that it may be "driven entirely from the pharmacopeia." Doubtless popular and medical opinions of the value of alcohol as a beverage or as a medicine have changed greatly in the past ten years. Doubtless, too, the medicinal as well as the convivial use of alcohol is likely to decline still further in the future. It does not seem, however, that this desirable consummation is likely to be hastened by the present volume, nor is it probable that alcohol will be "driven from the pharmacopeia" sooner than other dangerous and valuable drugs.

*Hypnotism and Treatment by Suggestion.* By J. Milne Bramwell, M.B., C.M. 12mo. Pp. xii, 216. New York: Funk and Wagnalls Company. 1910.

This little volume gives an interesting account of the history of hypnotism in a few pages and cites a considerable number of cases in the author's practice which have been benefited by suggestive treatment. While there is nothing new in the book except the presentation of personal experience along familiar lines, it is a clear and fair argument in favor of suggestive treatment. The author has been one of the leading authorities on hypnotism in London since the revival of the subject some twenty years ago, but, in spite of all the treatises that have appeared since the first publications of Liébeault and Bernheim, hypnotism seems unable to maintain a very important position among our therapeutic resources.

## RECENT PROGRESS IN SYPHILIS.

THE past decade has been one of amazing progress in medical science. Of all the diseases the knowledge of whose nature, cure and prevention has been advanced in that time, probably none is more important than syphilis. Ten years ago it was taught that the bacillus of Lustgarten was the etiologic agent of this infection; its diagnosis was based solely on history and clinical signs; its treatment was by mercury and the iodides. The discovery of Schaudinn's spirochete, the *treponema pallidum*, as the real causative organism was the first step towards a proper understanding of the disease. Later the announcement of the Wassermann reaction led to more precise methods of laboratory study and diagnosis. Still more recently the appearance of the Ehrlich-Hata salvarsan has added a new stimulus to the comparative study of methods of treatment and consideration of their relative merits. The mass of literature provoked by the exposition and discussion of these matters is altogether too vast for a busy practitioner to cope with, and he must, therefore, rely for information chiefly on the summaries and abstracts of progress which appear from time to time in medical periodicals. One of the most useful of these which has recently been published is an article in the current number of the *Quarterly Journal of Medicine*, by Dr. Hugh Wansey Bayly, entitled "A Résumé of Some of the Evidence Concerning the Diagnostic and Clinical Value of the Wassermann Reaction." This paper is of particular interest in connection with some facts reported in a letter from the Philippines, printed in another column of this issue of the JOURNAL, and a brief review of Dr. Bayly's conclusions may prove instructive.

In the first place, from comparison of the data of a number of different observers, Bayly finds that a positive reaction may generally be considered as diagnostic of syphilis. Negative reactions are of less value, though the frequency of their occurrence in undoubted syphilis varies according to the stage of the disease and the nature and duration of treatment.

In the second place, given the diagnosis, the Wassermann reaction is of the greatest value as a control of treatment, since it tends steadily to become negative in proportion to the efficacy of such treatment. The diminution in the amount of complement fixed is regarded as a measure of the progress made. Judged by this test, "potassium iodide and the early arylarsonates (atoxyl, soamin and orsudan) seem to have but little if any" effect on the reaction. Mercury is of far greater therapeutic value. "Pills and suppositories seem to be the slowest and least efficient forms of treatment, and inunctions and intramuscular injections of insoluble compounds, the quickest and most efficient." Salvarsan ("606") has as yet been in use too short a time for positive statements as to its efficacy, but the indications are that it is our most powerful, rapid and valuable agent in the treatment of the disease. "Nearly all authorities agree that, in future, treatment, whether by mercury or '606,' must be regulated by the Wassermann reaction," which is of especial value in determining cure with reference to marriage. Bayly considers also that "the reaction is of great value in obstetric practice as a means of diagnosing latent syphilis in the mother; for, if positive, energetic antisyphilitic treatment holds out great hopes of the birth of a full time and healthy child." Its bearing on late manifestions of syphilis of the nervous system is also apparent.

In the third place arises the most important question as to the specificity of the reaction. That the reaction does occur in other diseases is true. "Of the diseases certainly not syphilitic in which a positive reaction is obtained, yaws heads the list, and in this disease as high a proportion of positives is obtained as with syphilis itself. Leprosy also produces a high percentage of positive results." Positive reactions occur frequently in trypanosomiasis and malaria, and occasionally in pneumonia and typhoid. If care be taken to rule out these infections, however, the value of the reaction as diagnostic of syphilis is not impaired.

In explanation of the occurrence of positive reactions in yaws, Bayly quotes from Wasser-

mann: "It should cause no surprise that the serum of patients suffering from other protozoal diseases gives a like reaction [to that of syphilis], considering the close relationship between spirochetes, trypanosomes and other protozoa." It is easily conceivable that such allied organisms should produce similar endotoxins, and the endotoxins are presumably the agents indirectly causing the reaction. Evidence of this may be cited in the fact that "occasionally a case is diagnosed as syphilis and gives a negative reaction, and yet after being on mercury a while a positive reaction is obtained. This is probably due to the fact that the mercury destroys numbers of the treponemata, whose endotoxins are then liberated and stimulate the production of the antibody, which is probably the substance that produces the positive reaction." Confirmatory evidence of the similarity, or even identity, of the endotoxins in syphilis and in yaws may be found in the reported great therapeutic value of "606" in the latter disease, as mentioned by our correspondent in the letter referred to above.

In diagnosis and in the control of treatment, then, the Wassermann reaction may fairly be regarded as of great and established medical value. With proper precautions regarding history and technic, the original method of Wassermann being probably the most reliable, we may consider, with Wassermann, that "in case of a positive reaction, it can be said with certainty that the investigated case is syphilitic. On the other hand, if the reaction be negative, syphilis cannot be excluded absolutely, but only with a probability of about 90%." With a test of such value for diagnosis and control, and with a new therapeutic agent of such apparent efficacy as "606," it should seem that the future offers increasing promise in the treatment and limitation of so serious a scourge as syphilis.

## COLLEGE WOMEN AS MOTHERS.

Failure of members of the most highly educated and supposedly, therefore, fittest classes to marry and produce offspring is frequently cited by foreboding speculators as evidence of so-called race suicide and degeneracy in this country. It is undoubtedly true that, for various reasons, college graduates of both sexes marry later and have fewer children than those not thus educated. What is much more important, and much harder to determine, is whether the children of such marriages suffer in quality as well as in quantity. In this connection there are some interesting statistics in the recently published Wellesley College Alumnæ Register. It appears that of all the graduates of this institution, less than a third have married. Similar statistics for Smith, Bryn Mawr and Vassar were prepared several years ago by Dr. Smith, of California, for the Association of Collegiate Alumnæ. At that time Dr. Smith found, from comparative study of these data and those of a similar number of non-college women from the same families, that approximately half of all college women marry and have an average of 1.65 children apiece, whereas the married non-college women had 1.8 children apiece. One interesting fact, brought out incidentally, was that of the children of the non-college women, less than 48% were males, whereas of those of the college women, over 55% were males. Perhaps this indicates that intellectual women are more likely, like Lady Macbeth, to "bring forth men children only." The fact may have some bearing on sex determination. Whether the change in proportion is desirable is another question.

Probably the two most detrimental physical possibilities, from a childbearing point of view, in the higher education of women, are failure of sexual development from overgreat mental activity at time of puberty, and tendency to later neurasthenic disturbances. In both these respects, however, the damage is less likely to be done in college than during the time of school preparation. Doubtless these are evils likely to right themselves in time by slow process of adjustment and survival. As a matter of fact, the prolific decline of college graduates seems dependent less on special causes than on general tendencies involving the whole of modern civilization. Whether or no college women make better wives and mothers as a result of their education is a question that lies beyond the power of statistics to answer.

## DECREASE OF SMALLPOX AS AN INDEX OF ENLIGHTENMENT.

Not only was the conquest of smallpox by vaccination the first great triumph of preventive medicine, but the continued reduction of its incidence and mortality by the same procedure remains one of the best standards and tests of enlightenment in any community. The amount of this reduction since the early days of vaccination has, of course, been enormous. In 1802, there were approximately 45,000 deaths of smallpox in Great Britain and Ireland, and this not

in a time of epidemic pestilence. When the disease was introduced on this continent, the native Mexicans and Indians perished of it literally by millions. It is gratifying that our recent invasion of the Philippines has not been attended by a similar result, but that instead the number of deaths was reduced by wholesale vaccination from over 6,500 annually to none in the year 1906–7.

But salutary measures, like prophets, are often least honored at home. During the six months ending Dec. 31, 1910, there were reported in the United States 9,262 cases of smallpox, with 203 deaths. Of these, 1,665 cases and 7 deaths were in North Carolina. In Oklahoma, there were in this time 1,187 cases, in Kansas 1,049, in Michigan 1,000, and in Texas 881 cases and 28 deaths. In some other states which make a better showing, the figures are invalidated by unreliability and incompleteness of registration. It is probably not too much to say that 9,000 of these cases and 200 of these deaths might have been prevented by universal protective vaccination. Their occurrence is a reproach to the communities in which they were permitted to happen. Such instances serve but to illustrate how lamentably popular ignorance and prejudice may impede the progress of medical salvation.

## SIR FRANCIS GALTON.

THE death in London, on Jan. 18, of Sir Francis Galton removes from the scientific world one of its most eminent figures. Beginning life, after an extended collegiate education, as an explorer, he became particularly interested in the problems of anthropology and biometry, and his studies in this field made him later a student, exponent and critic of doctrines initiated by Darwin and others of the great nineteenth century school of English thinkers. The culmination of his studies in such subjects was his foundation in 1905 of the Laboratory of Eugenics at University College, London, the first practical attempt to apply the principles of our knowledge in heredity and evolution to the problems of race betterment. Dr. Hart has said, with a touch of Scotch acerbity, that "the founder of biometry in Britain is Galton, and Karl Pearson is its prophet"; but Dr. Saleeby has more reverently and appropriately referred to Galton as "the august master of all eugenists." Whatever time may decide of the merit of his work or the accuracy of his laws, it is certain that he possessed the noble and serious earnestness which has made so many English scientists not only great scholars but great men.

## MEDICAL NOTES.

LARGE SEIZURE OF OPIUM IN SAN FRANCISCO. — Report from San Francisco states that on Jan. 18 the United States customs officers seized in that port $20,000 worth of opium. This is said to be the largest seizure of the kind ever made in the city.

TYPHOID FEVER IN MOSCOW. — It is reported from Russia that typhoid fever is now epidemic in the region about Moscow, and that there are in that city at present over 700 cases. The municipality of Moscow is said to have appropriated the equivalent of $50,000 for the purpose of combating the further spread of the disease.

DISCOVERY OF A NEW ELEMENT. — It is announced from Paris that M. Urbain has reported to the Academy of Science in that city his discovery of a new element, which he has named celtium. It is said to resemble the element lutecium which he discovered in 1908.

PRECAUTIONS AGAINST SMALLPOX IN PHILADELPHIA. — It is reported from Philadelphia that following the recent death in that city of a small boy from malignant smallpox, the entire vicinity of his home was quarantined and nearly three thousand persons in that district were vaccinated. The twelve other occupants of the infected house were sent to the detention hospital for observation.

"THE DOG IT WAS THAT DIED." — Report from Baker City, Ore., states that on Jan. 19 a band of mad coyotes, supposed to be infected with rabies, invaded the neighboring village of Durkee, biting a large number of people and dogs. After killing or driving away the coyotes, the local police are said to have shot every dog in town to prevent possible spread of the infection. What was done for the human victims is not stated. Perhaps, to complete the analogy, they will, like Goldsmith's man of Islington, "recover of the bite."

END OF CHOLERA EPIDEMIC IN TURKEY. — Report from Turkey states that the epidemic of Asiatic cholera in that country has now been officially declared at an end, and that the shipping quarantine against Constantinople has been raised. It is said that since the outbreak of the infection last September there have been 1,318 cases and 793 deaths of the disease. It is interesting to note that practically all the foreign epidemics of cholera show a death-rate of about 50%.

A PRECOCIOUS GRANDFATHER. — It is reported from Raleigh, N. C., that Victor Beyson, of the

neighboring town of Spencer, in Rowan County, has just become a grandfather at the age of thirty-three. Beyson is said to have married, at the age of fourteen, a girl of thirteen and one-half. Their eldest son, now sixteen years old, married last spring a girl of fifteen, who has recently given birth to her first child. All the persons concerned are said to be of pure-blooded English descent. Such premature matrimony is rather rare in this race, and, however its result may seem to operate against the decline of population, is hardly to be recommended as a practice from the point of view of eugenics.

Retirement of a Naval Surgeon. — The committee of the National Senate on naval affairs has recently reported favorably a bill to place on the retired list of the United States Navy Dr. James Henry Payne (Harvard A.B. 1886, M.D. 1889), of Boston. Dr. Payne entered the navy in 1898 as a volunteer surgeon during the war with Spain, and in 1900 was commissioned assistant surgeon in the regular service.

Changes in the Journal of Experimental Medicine. — It is announced that beginning with its thirteenth volume this year, the *Journal of Experimental Medicine*, published in New York by the Rockefeller Institute for Medical Research, will be issued monthly instead of every other month as heretofore. There will now be two volumes a year. Dr. Benjamin Terry is to take the place of Dr. Eugene L. Opie as associate editor of the magazine with Dr. Simon Flexner.

Medical Field Training Camps. — It is reported from Washington, D. C., that the United States War Department has disapproved, for lack of sufficient funds, "the recommendation of the Surgeon-General of the army for conducting two camps of instruction during the coming summer for the benefit of medical officers of the organized militia." During 1909 there were several such camps, at which temporary field hospitals were erected and instruction given in their administration and in the field discipline and duties of medical and ambulance corps. The project was considered highly successful, and its repetition this year was urgently recommended, but the demand on available army appropriations is said to be too great to make this possible.

Accidental Cure of Uncinariasis. — A story, good enough to be true, has recently been told of an anemic youth in North Carolina who, in 1867, went to a doctor for some medicine. Meaning to give him some simple tonic, the busy, or perhaps lazy, and certainly careless, physician told his patient to take a dose from the second bottle on the first shelf of the medicine closet. The boy got the wrong bottle and took a large potion of oil of thyme. When he recovered from the violent purging which followed, his health became miraculously improved and he grew into a robust and vigorous man. Thus occurred the first, and accidental, cure of an unsuspected, undiagnosticated case of uncinariasis.

Progress of the Plague in China. — The epidemic of bubonic plague in Manchuria and northern China is apparently steadily extending. Harbin, Fudziadian, Mukden, Kirin, Tieling and Kwan-Cheng-Tze are all centers of the disease, from which infection is being spread in every direction. Ignorance and superstition of the natives blocks the efforts made by physicians and officials to check the scourge. On Jan. 15 the number who up to that time had died in Manchuria alone is said to have reached 1,752, and since then from 150 to 200 deaths have been reported daily. Most of these are Chinese, but several Russians and one Frenchman have also died of the disease. The Chinese quarantine instituted at the Great Wall has not sufficed to prevent the plague from passing to the southward, and deaths from the disease have already occurred in Chin-Wang-Tao, and at Pekin. Advices from Che-Fu state also that the infection has been carried by junks across the gulf of Pe-Chi-Li and seems likely to extend through Korea. In the provinces of Anhui and Kiangsu the situation is complicated by flood and famine. One million Chinamen are said to be starving in that district, and an appeal has been made by missionaries for a fund of $2,000,000 to provide them with food.

## BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, Jan. 17, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 46, scarlatina 44, typhoid fever 2, measles 51, smallpox 0, tuberculosis 71.

The death-rate of the reported deaths for the week ending Jan. 17, 1911, was 15.90.

Boston Mortality Statistics. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Jan. 21, 1911, was 243, against 255 the corresponding week of last year, showing a decrease of 12 deaths, and

making the death-rate for the week, 18.39. Of this number 119 were males and 124 were females; 234 were white and 9 colored; 131 were born in the United States, 106 in foreign countries and 6 unknown; 55 were of American parentage, 149 of foreign parentage and 39 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 51 cases and 4 deaths; scarlatina, 45 cases and 4 deaths; typhoid fever, 4 cases and 0 deaths; measles, 68 cases and 2 deaths; tuberculosis, 44 cases and 25 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 34, whooping cough 2, heart disease 32, bronchitis 5. There were 10 deaths from violent causes. The number of children who died under one year was 34; the number under five years, 54. The number of persons who died over sixty years of age was 74. The deaths in public institutions were 96.

A MILK DEALER FINED. — In the Superior Criminal Court at Boston last week, a dealer of this city was fined $50 for having in his possession, with intent to sell, milk not up to the standard required by law. He had been previously fined $20 in a lower court, but had appealed from the decision.

PROPOSED HOSPITAL FOR INCURABLES. — As a result of its recent investigations, the Massachusetts State Board of Charity reported last week its opinion that the proposed establishment of a state hospital for incurables is unnecessary. The board believes that such cases should be cared for by their own cities and towns.

ADDRESS BY DR. WILEY. — At a meeting of the Economic Club, at Worcester, Mass., on Jan. 19, Dr. Harvey W. Wiley, of Washington, D. C., in an address on "The Economy of Pure Food," opposed the selling of food products in small packages at a fixed price, and advocated the sale by weight of all such products, including eggs.

MEDICO LEGAL EXAMINATION OF BLOOD AND BLOOD STAINS. — At the meeting of the Rhode Island Medico-Legal Society, Jan. 19, Dr. W. G. Dwinell, of Pawtucket, presented a comprehensive paper on the subject, "The Medico-Legal Examination of Blood and Blood Stains." The paper dealt particularly with the reactions of human and rabbit's blood in tests made and is a valuable addition to the compilation of data being prepared in connection with the legal side of the medical profession.

MEETING OF MEDICAL WOMEN. — The thirty-third annual meeting of the New England Hospital Medical Society of Women, held in Boston on Jan. 18, was attended by forty-two members. The following officers were elected for the ensuing year: President, Dr. Blanche A. Denig; vice-president, Dr. Sarah Stowell; treasurer, Dr. N. Louise Lawrence; secretary, Dr. Margaret L. Noyes.

MEETING OF ST. LUKE'S GUILD. — A quarterly meeting of St. Luke's Guild of Catholic Physicians was held in Boston last week. Dr. Thomas Dwight, who presided, read a number of letters of greeting from similar bodies in London, Italy, Spain and the Netherlands. Addresses were made by Dr. Thomas F. Harrington on "The Preservation of Life," and by Dr. Frederick W. Johnson on "Ectopic Gestation."

A CENTENARIAN. — In the issue of the JOURNAL for Dec. 29, 1910, we noted the celebration on Dec. 20 by Mrs. William T. Temple, of Reading, Mass., of the supposed centennial anniversary of her birth. Mrs. Temple died on Jan. 18. She is survived by two of her five children and by nine grandchildren.

A LIVING CENTENARIAN. — Daniel Short, of Cambridge, Mass., who alleges that he was born on Nov. 11, 1810, is still employed as driver of a dump cart in that city. Twice recently he has received minor injuries by falling from his cart, but has returned immediately to his work, declaring that while he lives he will not be idle. Similar praiseworthy energy and persistence might to advantage be exhibited by many persons not of his advanced years.

TRANSMISSION OF POLIOMYELITIS. — In a recent report to the Connecticut State Board of Health, Prof. Herbert W. Conn, of the Biological Department of Wesleyan University, who has been investigating the recent epidemic of poliomyelitis in Middlesex County, of that state, expresses his belief that the disease is transmitted by fleas, which, as intermediate hosts, are carried from one household to another in the fur of cats and dogs.

BEQUESTS TO MAINE INSTITUTIONS. — Among numerous charitable bequests in the will of the late Mrs. Gardner Blanchard Perry, filed on Jan. 16 for probate at Newport, R. I., is one of $5,000 to the Home for Aged Women at Bangor, Me., and one of $4,000 to the Eastern Maine General Hospital at Bangor for the maintenance of a free cot. Mrs. Perry died in December, 1910, at Pasadena, Cal.

Mange as a Contagious Disease. — At a hearing last week before the committee of the Massachusetts Legislature on agriculture, Dr. William C. White, of Newtonville, Mass., an agent of the State Cattle Bureau, advocated the inclusion of mange in the list of contagious diseases affecting horses and cattle. This disease is said to be spreading among horses and milch cows, and is believed to be of infectious origin.

A Leper in Boston. — A case of leprosy was discovered in Boston last week in the person of a Japanese who recently came to this city from the West. Pending his removal to the leper colony on Penikese Island, he has been sent to the detention hospital on Southampton Street, and the house in which he was lodging has been fumigated by the board of health. This is the first case of leprosy in Boston since the discovery of two cases here over a year ago.

Objection to Free Individual Cups. — At a hearing last week before the committee of the Massachusetts Legislature on public health, the counsel of certain railroads made objection to the proposed bill requiring that every passenger car in this state shall be provided with free individual drinking cups to the number of twice its seating capacity. Considering the cost of such a procedure, this objection on the part of railroad companies seems well founded.

### NEW YORK.

Appointment of Dr. Wm. B. May. — Dr. William B. May, of Buffalo, has been appointed director of the Division of Communicable Diseases of the State Department of Health. Dr. May is well qualified for the position, having been associated with the health department of the city of Buffalo for the past twelve years.

Bequests. — By the will of the late John W. Ellis, of New York, $10,000 is left to the Nursery and Child's Hospital. The bequest is made in memory of the testator's wife, Caroline S. Ellis, and is to be added to the building fund of the institution.

By the will of the late Ludwig Rothschild, of New York, $500 each is left to the German Hospital, Mount Sinai Hospital, the Montefiore Home and Hospital for Chronic Invalids, and three other charities.

Meeting of Medical Association of Greater City of New York. — At the annual meeting of the Medical Association of the Greater City of New York, held Jan. 16, Dr. Thomas Darlington, recently head of the city health department, was elected chairman for the Borough of Manhattan. At this meeting Dr. R. L. Watkins demonstrated a remarkably ingenious portable photomicrographic camera, the planning and construction of which has occupied him for many years. It will photograph any microscopic object, and the apparatus contains a microscope, camera, box, arc and incandescent lamps, and a rheostat weighing only a few ounces. The object to be photographed can be viewed either in the usual way through the microscope alone, or on a mirror, with both eyes open, without looking through the microscope.

A Possible Cure for Cancer. — It is announced from Albany that Dr. Harvey R. Gaylord, of the State Cancer Laboratory at Buffalo, has made a report in which he states that after ten years of research work he is prepared to furnish a serum which it is believed is curative of cancer, one patient having been entirely cured of the disease by means of it. No particulars are given. In accordance with a recommendation made in the report, State Senator Loomis, on Jan. 19, introduced into the Legislature a bill appropriating $65,000 for the erection of a cancer hospital adjoining the laboratory in Buffalo. Among the trustees of the institution named in the bill are Drs. Roswell Park and Charles Cary.

Scholarship in Ophthalmology. — A scholarship in ophthalmology has been founded by William A. DuBois, Matthew B. DuBois and Katherine DuBois, sons and daughter of Dr. Abram DuBois, who have presented to Columbia University the sum of $18,000 to be used as a fund for this purpose. This is to be known as "The Dr. Abram DuBois Memorial Fund." The scholarship is open to graduates of the College of Physicians and Surgeons who have satisfactorily completed a term of service in an eye hospital and who have given evidence of serious intention of pursuing ophthalmology as a specialty. The holder of the scholarship is expected to devote himself to postgraduate studies, preferably of a scientific character, connected with ophthalmology, in foreign and American universities. The income amounts to about seven hundred dollars a year. The bestowal of this scholarship is in the hands of a committee consisting of the Professor of Ophthalmology, the Dean of the Medical School and Dr. Edward L. Partridge.

CONTINGENT BEQUEST TO RED CROSS HOSPITAL. — Under the will of the late William T. Wardwell, of New York, for many years the treasurer of the Standard Oil Company, and who was the Prohibition candidate for governor in 1900, the New York Red Cross Hospital will receive $100,000, provided it continues its policy of the non-use of alcohol as a medicinal agent. The will prescribes that the hospital shall avoid even tinctures when equally desirable action can be obtained with fluid extracts or alkaloids, and shall reduce to a minimum the use of other potent or narcotic drugs which might induce habit or produce injurious after-effects. Mr. Wardwell has always been the principal benefactor of the Red Cross Hospital, and to his liberality it is indebted for its present commodious building on Central Park West. His gifts have been made on the condition that alcohol should not be employed, and the will provides that three arbitrators shall decide whether the hospital has been true to its tenets — one selected by the directors, one by the trustees under the will and a third chosen by the two bodies.

THE COLD STORAGE EVIL. — In his inaugural address, delivered on Jan. 17, Governor Woodrow Wilson, of New Jersey, expressed himself very emphatically on the cold storage evil. "It is estimated," he says, "that most of the food supply of the people of Northern New Jersey, and half the food supply for New York City, is kept in cold storage warehouses in Hudson County, awaiting the desired state of the market. . . . The result is not only to control prices, but also to endanger health, not because of the effect of too long storage upon the foodstuffs themselves, but because of the deleterious effects of taking them out of cold storage and exposing them to thaw in the markets. The least effect is loss of nutritious quality; the worst, the generation of poisons by decay and even putrefaction. No limit at all is put upon this abuse by law, and strong influences are brought to bear by interested parties to prevent the enactment of remedial legislation. . . . I earnestly urge that the Legislature take up this important matter at the earliest possible time and push some effective law of inspection and limitation to enactment. It would give me great pleasure to sign a bill that would really accomplish the purpose."

OPENING OF EXTENSION TO CARNEGIE LABORATORY. — The building which has been erected as an extension to the Carnegie Laboratory of the University and Bellevue Hospital Medical College was formally opened on Jan. 10. This addition, which is largely the gift of Andrew Carnegie, who donated the original laboratory, cost, with the land, $125,000. At the dedicatory exercises addresses were made by Mr. Carnegie; Prof. William H. Welch, of Johns Hopkins University; Herman M. Biggs, secretary of the faculty of the New York University Medical School; and Jerome D. Greene, general manager of the Rockefeller Institute. Dr. Egbert Le Fevre, dean of the Medical School, presented to Mr. Carnegie, on behalf of the laboratory staff, four volumes, specially bound in morocco, containing researches in medical science published by members of the staff. Mr. Carnegie described this institution as one of his "very first children," and spoke of the wonderful advances in bacteriology and other branches of research which had been made during the twenty-five years of its existence. In concluding his remarks he intimated that he might be willing to make further gifts to the University Medical School if its needs required them. In the course of his address, Dr. Biggs said that the laboratories of the New York City Health Department were the first municipal laboratories in the world and that their establishment followed and was inspired by the original Carnegie Laboratory. Largely on account of the work done in them, there were 50,000 fewer deaths every year in the city than would occur if the death-rate were the same as eighteen or twenty years ago. The exercises were held at three o'clock in the afternoon, and at 5 P.M. the first of this year's course of lectures on the Herter Foundation was given by Dr. H. R. Cushny, now professor of pharmacology in the University of London.

POLLUTION OF BRONX RIVER. — At the request of the boards of health of the towns of Scarsdale and Greenburgh, Westchester County, the State Department of Health recently made an investigation of the pollution of the Bronx River from White Plains to Bronxville. So many sources of contamination were found that it was declared by the officials of the department that the present pollution of the stream sets up a condition which constitutes a public nuisance along the Bronx adjoining the towns of Scarsdale and Greenburgh and along the major portion of its flow adjoining the city of Yonkers and the town of Eastchester. It is stated, however, that this condition of nuisance will be almost wholly if not entirely eliminated by the discharge of sewage from the

various systems and sewage-disposal plants into the Bronx Valley trunk sewer upon its completion, rather than into the Bronx River, as at present, and the authorities of the districts concerned have been advised to make connections between their respective sewerage systems and this trunk sewer at the earliest possible moment. The Bronx Valley trunk sewer is fifteen miles long, three miles of it being in tunnel, and its completion is expected during the present month, when it will be ready for use as an outlet for the sewage from the towns and villages through which it passes. This is a matter of no little interest to the city of New York, as the Bronx, after passing through Westchester County, flows through the great Bronx Park and thence through the Borough of the Bronx until it empties into Long Island Sound.

## Current Literature.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

JAN. 14, 1911.

1. HALL, J. N. *Why the General Practitioner should Study Surgical Diagnosis of Gastric and Duodenal Ulcer.*
2. *ENGMAN, M. F., MOOK, W. H., MARCHILDON, J. W. *Report of Sixteen Syphilitic Patients Treated with Ehrlich's Salvarsan.*
3. *RIES, E. *Diagnosis of Operability of Carcinoma of the Cervix Uteri.*
4. FREDERICK, C. C. *Use of the Cautery in Treatment of Carcinoma of the Cervix.*
5. *JACOBSON, J. H. *Results Obtained by the Radical Abdominal Operation for Carcinoma of the Uterus.*
6. *SAMPSON, J. A. *The Participation of the Tissues Adjacent to the Uterus and of the Pelvic Lymphatics in Uterine Cancer.*

9. BIRD, M. D. *Apparatus for Proctoclysis.*
10. NORTHRUP, W. P. *New Reflex Sign in Meningitis. Diagnosis.*
11. BURNETT, C. T. *Apparatus for the Preparation of Bacterial Suspensions.*
12. PLONDKE, F. J. *The Treatment of Puerperal Eclampsia.*
13. PUSEY, W. E. *The Situation as Regards Salvarsan.*

2. Engman, Mook and Marchildon, analyzing sixteen cases of syphilis treated by salvarsan, report the development of one case of nephritis which later cleared up. Two cases of nerve syphilis were worse than before injections. None of the patients showed symptoms of arsenical poisoning. The drug had remarkable effect on the cutaneous lesions.

3. Ries makes some very valuable suggestions in reference to the operability of cancer of the cervix. If the cystoscope shows that the carcinoma has grown through into the bladder it has been of value, but the other conditions found in the bladder, such as edema, bullous edema and distortion of the bladder, are not reliable. They may be due less to the carcinomatous invasion of the bladder than to the infected condition of the cancer. It is one of the important advances achieved by the performance of the radical abdominal operation that we know now that a uterus which appears immovable on combined palpation may be perfectly operable, because in a number of cases the fixation is not due to carcinoma, but to chronic inflammatory thickening of the ligaments. Every radical abdominal operation for carcinoma of the cervix should be begun as an exploratory operation, for a rapid review of the liver, abdominal glands and bladder may show metastatic conditions which would contraindicate further operation. The condition of the glands is very difficult to interpret correctly. Large glands may or may not be cancerous, and small glands are not necessarily free from cancer.

5. Jacobson gives the following figures as to the operability of uterine cancer. Among continental surgeons, including Wertheim's figures, there is an operability of 65.17%, a primary mortality of 19.94%, a permanent cure from three to five years in 40.72% and an absolute cure in all cases of 21.14%. The American average is operability 35%, primary mortality 15.17%, permanent cures after five years 8.39%, and absolute cure about 1%. A comparison with results obtained by other forms of operation shows that the best results are obtained from radical abdominal operations.

6. Sampson says that the most radical operation consistent with a "permissible primary mortality" is indicated, especially in early cases. It is impossible to remove at operation all of the lymph nodes which may be infected, and at best we must be satisfied with an incomplete removal. We should do the most thorough operation, however, which the patient will stand. The most important aid to the treatment is earlier diagnosis. [E. H. R.]

THE LANCET.

DEC. 10, 1910.

1. GOULD, A. P. *The Bradshaw Lecture on Cancer.*
2. *PITT, G. N. *The Bradshaw Lecture on the Results of Bronchial Obstruction.*
3. *MCINTOSH, J., AND FILDES, P. *The Theory and Practice of the Treatment of Syphilis with Ehrlich's New Specific, "606."*
4. NEWBHOLME, H. P. *A Pedigree Showing Bi-Parental Inheritance of Webbed Toes.*
5. NORMAN, R. H. *Note on an Obscure Case of Peritonitis.*
6. MACNAUGHTON-JONES, H. *Uterine Cervical Polypus Undergoing Malignant Degeneration.*

2. Pitt, in a long and profusely illustrated article, discusses the results of bronchial obstruction. He first classifies some of these results in eleven headings and then discusses the causes of bronchial obstruction as follows: *External* causes: (1) Aneurysm, (2) malignant disease, (3) enlarged glands, (4) gummata, (5) abscess, (6) dilated left auricle. *Internal* causes: (1) Bronchiolitis, (2) syphilitic ulceration with scarring, (3) primary malignant disease of a bronchus, (4) foreign bodies in the bronchus. He goes over these different causes in detail and presents numerous illustrative cases. The paper is of considerable interest and covers the ground well.

3. McIntosh and Fildes add one more article to the many already published on "606." They discuss the underlying principles, the method of technic, precautions to be followed, dosage, effect on the lesions, effect on the Wassermann reaction and relapses. They present numerous illustrative cases. [J. B. H.]

DEC. 17, 1910.

1. STEPHENSON, S. *A Lecture on the Aftermath of Eye-strain.*
2. *INMAN, A. C. *The Specific Diagnosis of Pulmonary Tuberculosis.*
3. WARRINGTON, W. B. *Note on Tuberculous Meningitis, with Especial Reference to the Invasion Symptoms when the Disease Occurs in Adults.*
4. *FRASER, H., AND STANTON, A. T. *The Etiology of Beri-Beri.*
5. KENNEDY, A. M. *Cases of Primary Carcinoma of the Appendix Vermiformis.*

2. Inman, in a most valuable paper, takes up the specific diagnosis of pulmonary tuberculosis. His conclusions are as follows: (1) In the early diagnosis of pulmonary tuberculosis the recent methods of concentration by means of antiformin should always be employed in the sputum and feces. (2) The difficulty of interpreting the results of the various tuberculin tests seriously limits

their value in the diagnosis of active pulmonary tuberculosis. (3) A positive opsonic index test is of undoubted value in the diagnosis of active pulmonary tuberculosis. A negative opsonic index test must be taken with reserve. The interpretation of the result rests with the clinician who can take into consideration all the additional factors in the diagnosis of the case. In this article Inman gives the technic of the various newer methods of sputum and feces examination, discusses Rosenberger's claim to have discovered tubercle bacilli in the blood of consumptives, bringing forward evidence of others chiefly not confirmatory of this; he gives various tables showing results of examination of feces and sputum; he discusses at length the various tuberculin reactions, skin, eye and subcutaneous, and at some length takes up the opsonic index test with a table of 100 cases. There is an extensive bibliography.

4. Fraser and Stanton, discussing the etiology of beriberi, believe that white polished rice when forming the staple of diet in man is the cause of beri-beri; when such rice is fed to fowls it produces in them a disease closely analogous to the disease in man. The addition of rice polishings to a diet of white rice is an effective preventive of the development of the disease in fowls. [J. B. H.]

5. MOLLISON, W. M. *Common Causes of Discharge from the Ears, and Its Treatment.*

1. Philip emphasizes the need of exercise as well as rest in the treatment of consumption. He brings out the point that consumption is a general toxemia and not a disease purely localized in the lungs; this toxin is particularly harmful to muscle and nerve tissue, as shown by the great wasting which occurs. He explains the gradual development of the work treatment at the Royal Victoria Hospital in Edinburgh, and gives the details of the system of badges patients wear according to the class and amount of work they are doing. Out of 109 patients now under treatment at this hospital, 103 have gained weight under this system of graduated exercises, and more than one third of the patients have reached the highest grade of activity.

3. Bolton describes the continuation of his experiments on gastric ulcer in cats. These ulcers, as previously described, he has been able to form by injecting a "gastrotoxic serum." His present paper is on the influence of diet upon the formation and healing of acute ulcers. He concludes from his investigations that (1) ulceration is the more rapidly produced in proportion as the gastric juice is allowed a longer period of contact with the stomach wall. (2) On a milk diet the epithelium grows more rapidly over the base of an ulcer than on a meat diet. (3) In meat-fed animals the base of the ulcer is frequently quite uncovered by new epithelium at the end of twenty days. (4) In treatment, the following principles should be observed: (*a*) During the early stages such food should be given which does not long remain in the stomach and which does not excite much juice. (*b*) The period of treatment should be at least three weeks in bed. (*c*) Starvation diet is not advisable as the general nutrition suffers too much. (*d*) High degrees of acidity which are often present should be counteracted by an alkali.

4. Graves and Bolton describe a case of thyroid grafting the essential features of which were: (*a*) Temporary improvement following thyroidectomy. (*b*) The occurrence of tetany after subtotal thyroidectomy in which the parathyroids had been preserved. (*c*) Cure of tetany by thyroid medication. (*d*) Persistence of dyspnea and tachycardia in spite of thyroidectomy. (*e*) Occurrence of tetany after thyroid grafting. (*f*) Cure of this by hypnotic suggestion. (*g*) Great amelioration of symptoms by thyroid grafting. [J. B. H.]

7. JUBB, A. A. *A Case of Dwarfism.*

1. Russell, in a general article on hyperacidity, describes its symptoms, pathogenesis and treatment, and in brief its relation to acute gastric ulcer, pyloric spasm, chronic ulcers and gastroptosis.

3. Hicks makes a plea for more general and patient investigation into the effects of chronic movable kidneys upon general health. He describes the various symptoms which may arise and urges early diagnosis and treatment. In regard to treatment after rest in bed, he advises the use of a carefully fitted truss or belt; he describes in detail the method of properly applying such a belt. He favors operation only after careful trial of other measures. [J. B. H.]

5. Seiffert reports a modification of Weichardt's test for syphilis in the serum of patients by means of a physicochemical method. The test depends upon titration to determine the acidity or alkalinity under certain conditions,

and in this article he explains the technic in detail. He has tried out the test with sera, using the Wassermann as a control. This test has always been positive when the Wassermann test was and occasionally it was positive when the Wassermann was negative.

He considers that it has some value in determining the quantity of immune bodies developed in a syphilitic individual. He hopes for further investigation by others with the test. [C. F., Jr.]

2. The fat found in the blood of diabetic patients is not from the subcutaneous fat as that frequently persists pretty well. The fat is composed chiefly of cholesterin and lecithin and is the result of the increased metabolism. More fat occurs as a result of the breaking down of cells and more is needed for the building up of fresh cells.

5. Variations in blood pressure due to psychic influences only increase the systolic pressure and do not affect the diastolic pressure as a rule. This applies also to cases in which the blood pressure is already elevated. [C. F., Jr.]

1. Melchior first mentions the work done by Drs. W. Mayo and Moynihan in bringing this disease before the medical world, proving its frequency and the importance of early diagnosis. The disease is much more common among males, the proportion between the sexes being about 3 to 1. Alcoholism seems to be a contributing, but by no means constant, factor. He takes up the different kinds of duodenal ulcers and their frequency. He finds no apparent relation between the acute duodenal ulcers, such as follow severe burns for instance, and these chronic ulcers of the duodenum. He reviews the symptoms and outlines methods of treatment, reporting several cases. He advises early operation when possible, first making sure of the diagnosis. He considers that prognosis must always be guarded, as even in the mild cases alarming symptoms may at any time occur. [J. L. H.]

3. By light percussion of the partly filled stomach, the patient standing, Roth could mark out the greater curvature with considerable certainty as confirmed by orthodiagraph.

8. During pregnancy there is a relative increase in excretion of all forms of nitrogen. The peptid-nitrogen excretion is often greatly increased soon after induced labor, diminishing only gradually thereafter. Alimentary levulosuria and peptid-nitrogen excretion run parallel for the most part during labor.

9. Dieballa reports two cases of primary pernicious anemia, each of which is instructive. The first, a man of fifty, was observed through a typical attack in 1894, in which the blood picture was reduced to 20% hemoglobin, 5,000,000 red corpuscles and a specific gravity of 1,029.5, with typical variation in red cells and leucopenia; he had reticular fundus hemorrhages, nosebleed and diarrhea, and for a week the icterus characteristic of hemolytic conditions in which urobilin alone is found in the urine. A number of medicaments had been tried without success, until salol, 5 gr. a day, was administered with concomitant rapid improvement. This patient remained well, being seen at frequent intervals, until thirteen years later, when he died, not of pernicious anemia, but of disseminated tuberculosis. The blood in the last illness showed 75% hemoglobin, 1.043 specific gravity, 3,080,000 red corpuscles and 2,800 white corpuscles. Post-mortem were found no evidences of pernicious anemia. This case the author regards as having recovered from pernicious anemia.

The second case, even more typical of the primary type of anemia, had been reduced to 28% of hemoglobin and 1,200,000 red corpuscles, when an improvement set in; but it was soon noticed that though the blood continued to improve in quality, the patient became weaker and a rapidly advancing tubercular process was found in the lungs, the patient dying of what proved to be disseminated tuberculosis. Just before death the blood picture showed 70% hemoglobin, 1.050 specific gravity, 3,500,000 red and 6,000 white corpuscles. Gross and histological findings in this case showed evidence of pernicious anemia, i. e., red bone marrow with excess of primitive cell forms of corpuscles, and hemochromatosis of organs. From this case the author argues that whatever the cause of pernicious anemia, it is not that of secondary types, and

suggests that there may even be some antihemolytic effect produced by the advancing tubercular process.

14, 15 and 16 are all concerned with the same work. The conclusions reached may be summarized: Both experimentally on dogs and rabbits and in cases of myxedema and exophthalmic goiter Lidsky shows coagulation of the blood to be slower and less complete in hyper- than hypo-thyroidism.

Fibrin is increased in the blood in myxedema, decreased in exophthalmic goiter and in experimental hyperthyroidism (sometimes three times as much in the latter as in the former).

Theoretical considerations on experimental basis show increased autolysis of proteids in hyperthyroidism.

18. Wenckebach makes remarks on exudative and adhesive pericarditis under three general headings, those under the second including original and important investigation.

(1) On artificial pneumopericardium in exudative pericarditis. The author states that it has been his custom for some time to replace a certain part of the fluid withdrawn from the thorax with sterile air, thereby preventing too sudden rearrangement of intrathoracic organs and impeding the rate of return of fluid. When, therefore, a case of tubercular pericarditis was twice tapped, with prompt return of fluid, and hemorrhage from the lung was caused, air to one half the volume of fluid withdrawn was placed in the pericardial cavity, with amelioration of both symptoms; moreover, this procedure relieved the precordial distress which tapping caused. Symptoms of artificial pneumothorax are unmistakable. An x-ray plate of the condition is appended.

(2) The paradoxical pulse. Study of tracings of heart, radial artery and respiration lead the author to make three classes of causes of this troublesome sign, the first from pressure outside the thorax, and he cites a man who on elevating his chest in respiration caught the subclavian artery between clavicle and first rib, thereby bringing on this condition. The second class has a dynamic origin; normally, the tendency is that there shall be a smaller output of blood from the heart during inspiration than expiration, due to the increased negative pressure in the pleural cavity during inspiration; abnormally, this condition may become apparent in a peripheral vessel in the following conditions: By simple deep breathing, by stenosis of the larynx, by limiting the respiratory surface, by the presence of exudate or enlarged heart, by weakness of cardiac musculature or dilation. He cites three cases of this class; in all, it is diagnostic that the pulse wave is greatest at the onset of expiration. The third class consists of cases caused by mechanical obstruction within the chest, and of these causes adhesive pericarditis is the most common. It is characteristic of the paradoxical pulse of this class that the greatest cardiac output occurs between expiration and inspiration, for at this time alone is such a heart in position to do its best work.

(3) On the diagnosis of adhesive pericarditis. The least important part of the paper. The author considers abnormal chest movements of the greatest importance, if pleural adhesions can be excluded. If the chest moves forward normally, adhesive pericarditis can be denied. The diagnosis of this uncommon condition has assumed a greater importance since the success of the operation of cardiolysis. [J. B. A.]

### ARCHIV FÜR KLINISCHE CHIRURGIE.

8. LEISCHNER, H., AND KÖHLER, R. *Homeoplastic Transplantation of Parathyroid Bodies and of the Thyroid Gland.*
9. TTROW, I. *Echinococcus of the Bones.*

4. Cholsoff presents an elaborate study of congenital diverticula of the bladder, describing their anatomy, clinical picture, diagnosis, course, prognosis and treatment, basing his discussion of the latter on a personal case which he reports at length. His conclusions are as follows:

(*a*) That diverticula of the bladder may be congenital or acquired, the latter being due to long-continued obstruction to evacuation of the bladder.

(*b*) That in congenital diverticula one ureter often opens into the diverticulum.

(*c*) That congenital diverticula are more often single.

(*d*) That they most frequently occur on the posterior wall of the bladder, less often on the lateral walls, most seldom on the anterior wall and the fundus.

(*e*) That the clinical picture in uncomplicated cases is very definite.

(*f*) That on the occurrence of infection, the symptoms of acute or chronic cystitis become prominent. Hydronephrosis, pyelonephritis or pyonephrosis are frequent complications.

(*g*) That diagnosis may most easily be made and established by the cystoscope.

(*h*) That diverticulum of the bladder has an average mortality of 83.1%.

(*i*) That treatment should be directed chiefly to securing free evacuation of the bladder.

(*j*) That to obtain this, the diverticulum must generally be removed.

(*k*) That to do this the peritoneal cavity must usually be opened, though low posterior and lateral diverticula may be removed through the perineum.

(*l*) That when the condition is accompanied by infection, the radical operation must be preceded by suprapubic drainage. [R. M. G.]

## Obituary.

### CHARLES O. BALLOU, M.D.

DR. CHARLES OLNEY BALLOU, who died of pneumonia on Jan. 18, at Providence, R. I., was born in Cumberland, R. I., on June 10, 1830. After graduating from Dudley Academy, in Massachusetts, he taught school for several years in this state and in Rhode Island. In 1850 he went to Detroit, Mich., where he entered the dry goods business, which he later continued at Providence, R. I., where he was married in 1857. In 1861 he enlisted in the Eleventh Rhode Island Volunteer Infantry and served with that command throughout the Civil War. After the war he went into business again, and for some time was engaged in the manufacture of cotton goods. In 1874 he took up the study of medicine, and in 1877 received the degree of M.D. from the Harvard Medical School. Since this time he had practiced medicine at Providence. He was a member of the Rhode Island Medical Society and of the Providence Medical Association.

### F. A. HARRIS, M.D.

DR. FRANCIS AUGUSTINE HARRIS, who died of cerebral hemorrhage on Jan. 18, at Winthrop, Mass., was born in Ashland, Mass., on March 3, 1845. He graduated from the Boston Latin School in 1862, and in 1866 received the degree of A.B. from Harvard College. He then entered

the Harvard Medical School, and after an interruption of three years, during which he taught at the Latin School, received his M.D. degree in 1872. In 1871 he served as a surgical house-officer at the Massachusetts General Hospital, and subsequently studied medicine for a time at Vienna. In 1873 he began the practice of his profession in Boston, and in 1877 was appointed medical examiner for Suffolk County, a position which he held for thirty years. He was a Fellow of The Massachusetts Medical Society. His widow survives him.

## Miscellany.

### MEDICAL POLICY OF THE BOSTON MILK AND BABY HYGIENE ASSOCIATION.

#### PURPOSE.

The purpose of the Milk and Baby Hygiene Association is "to improve the general milk supply, to encourage breast feeding, to provide milk properly modified for babies who cannot be nursed and to furnish advice and teaching in hygiene and the care of babies."

In carrying out these principles the Association intends to supplement and assist and not to duplicate or interfere with the work of private physicians or of hospital clinics or other organizations. Our work is prophylactic, not clinical. We care for well babies. We do not treat sick babies. We invite the hearty co-operation of all physicians and organizations.

#### MEDICAL DIRECTOR.

The management and supervision of all medical matters is in charge of a medical director, who in turn is responsible to the Medical Committee for the principles involved. The medical director has charge of and supervises all matters of hygiene, medical ethics and medical management. The medical director appoints and discharges conference physicians, subject to the approval of the Medical Committee.

The medical director provides for substitutes for conference physicians and stands ready himself to fill vacancies when necessary. He has complete charge of conferences and visits them often enough to keep up an *ésprit du corps* and to see that discipline is maintained.

In conjunction with the Nurses' Committee, the medical director employs and discharges nurses and supervises them during milk-distributing hours.

The medical director assumes responsibility for the proper conduct of classes for girls that may be conducted in high schools or elsewhere, and secures instruction for the fathers in the different stations.

The medical director relates the work of the Association as closely as possible with the various children's clinics of Boston and with organisations similar to the Milk and Baby Hygiene Association in other cities for the purpose of co-operation and mutual benefit.

#### CONFERENCE PHYSICIANS.

Conference physicians are responsible to the medical director and are appointed and discharged by him subject to the approval of the Medical Committee. The conference physicians are in charge of the conferences held in their respective stations. They control the feeding of all babies taking our milk who are not under the supervision of outside physicians. The conference physicians do not write prescriptions.

No proprietary food, as such, is ordered by conference physicians.

#### NURSES.

The nurses are chosen and appointed by the Nurses' Committee. They are responsible to the medical director on medical matters and to the director on administrative matters. One or more nurses are in charge of each station.

They supervise the distribution of the milk and assist the conference physician at the conferences, visit the homes and supplement and elaborate by personal efforts the instructions given by the conference physicians.

They do not take cultures.

They are not allowed to visit babies taking our milk when the child becomes ill and some other nurse is attending.

The nurses are subject to the policy and rules formulated by the Nurses' Committee.

#### MILK STATIONS.

Our milk stations are located as far as possible in distinct districts and near centers of congestion. The milk stations serve as milk dépôts and headquarters for conferences, lectures and other activities.

##### *Milk Distribution.*

The milk is distributed at the stations under the supervision of the station nurse, between eight and nine every morning. We supply clean milk, whole, modified and fat free, barley water and whey at cost.

##### *Milk Supply.*

The milk distributed by the Association comes from farms which are carefully inspected each month by the medical director or his representative.

The methods of transporting the milk, the central receiving, modifying and distributing plant, are under medical and bacteriological supervision. The whole milk, modified milk, fat free milk and whey are pasteurized. The whole and modified milk is inspected and tested in regard to bacterial count and percentages of composition at least once a week. The milk is purchased on contract after bids have been asked on published specifications.

Modified milk may be ordered through our stations for home delivery outside of Wards 1–10 and 12–15.[1] Such orders are stopped auto-

[1] Home deliveries within the wards covered by our stations may be had when the family is unable to send for the milk.

matically after one month unless renewed by a doctor's prescription.

*Conferences.*

One or more conferences are held weekly in each station.

At these conferences the conference physicians instruct the mothers in matters of hygiene and the care of the baby along prophylactic lines, using as far as possible the class method and avoiding duplication of the instructions given in out-patient clinics along clinical lines.

*Lectures.*

Lectures and talks to mothers and fathers are given at each station as frequently as possible.

ACCEPTANCE OF CASES.

Breast-fed babies may be referred to the stations for the supervision and instruction of the mother. Any well baby whose mother is unable to nurse it may be sent to our stations to secure milk and for the instruction of the mother.

Physicians wishing to send cases to the Association are provided with a card on which to state the formula they desire and whether or not they wish to continue to control the feeding of the case.

If the physician wishes to supervise the feeding of the case, the baby and mother may still have the benefit of the instruction and supervision of the conference physician and station nurse.

If the physician does not wish to control the feeding, and in all cases coming to the stations indirectly, the feeding of the baby and instruction of the mother at conferences and in the home is under the supervision of the conference physician and station nurse.

All babies obtaining milk from our stations or attending conferences are registered, but those whose feeding is not under the supervision of the conference physicians are counted separately in our vital statistics.

DISCHARGE OF CASES.

Well babies are continued under our supervision as long as deemed advisable by the medical director.

When a baby under our care becomes ill, it is referred back to the private physician or clinic referring the case to us. A card is sent with the case, stating name, address, station and formula which the baby is then taking. A return postal is attached, to be filled in and returned to the station by attending physician, giving date of discharge, diagnosis and formula advised, or, in case of death, the date, place and cause.

Cases which come to us other than through a private doctor or hospital clinic, and, where there is no family physician, if able to pay for a doctor's services, are given a list of all the conference physicians with their addresses. These cases, if unable to pay for a physician's services, are referred to the nearest hospital clinic or advised to call the district doctor. A case sent to a clinic or private physician becomes the patient of the hospital or physician to whom sent until returned to us.

The above outline of medical policy has been formulated and endorsed by the Medical Committee of the Milk and Baby Hygiene Association.

## NEW YORK ACADEMY OF MEDICINE.

### EDWARD N. GIBBS MEMORIAL PRIZE.

THE New York Academy of Medicine, 17 West 43d Street, New York City, announces the following new conditions of the granting of the Edward N. Gibbs Memorial Prize.

I. The Council of the New York Academy of Medicine is to appoint a permanent committee of award, consisting of five of its members, to be known as the Edward N. Gibbs Prize Fund Committee.

II. The said committee is to have the selection of the candidates and the awarding of the prize.

III. The method of award is as follows:

(1) The committee shall advertise the prospective award at intervals of not less than two years in appropriate medical journals, and otherwise.

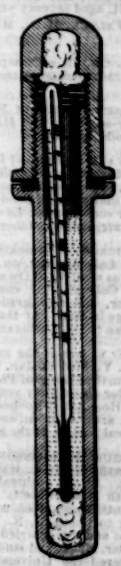
(2) Candidates must be physicians of not less than three years' experience since graduation in clinical and laboratory work; must be residents of the United States; and shall furnish the committee with evidence of research already performed and of ability to prosecute the special researches for which the prize is founded.

(3) Such researches may be conducted in any hospital or medical laboratory approved by the committee, wherever it may be situated.

(4) The researches shall comprise original work only in any or all of the following subjects: The causation, pathology and new methods of treatment of diseases of the kidney.

(5) From the applicants the committee shall select the one offering the best credentials as to ability to conduct original investigation, and to him shall be awarded from time to time during the research the income of the prize fund for such time as may have been occupied by the research, providing, however, that the total time shall not exceed three years, and provided that the committee shall at all times retain the power to reject unsatisfactory work from the award. It is understood, moreover, that the expenses of advertising and of publication of the researches be met from the income of the prize fund; and that when no research is forthcoming, the income for the current year be not awarded, but added to the principal of the prize fund.

(6) The completed research shall be presented in the form of a thesis and published under the auspices of the New York Academy of Medicine, bearing title substantially as follows:



"The Edward N. Gibbs Memorial Prize for Original Research in Diseases of the Kidney awarded through the New York Academy of Medicine. A Thesis upon the ——— of the Kidney by ———, M.D. Published under the direction of the New York Academy of Medicine."

(A brief note should be published with the thesis, setting forth the object of the Memorial Prize.)

It should be understood for all time that it is the fundamental purpose of the donors to promote the study of the diseases of the kidney with the object of relieving human suffering, but as it is impossible to forecast the direction of special scientific research, it should be left within the discretion of the permanent committee of the Academy to modify the details of method of award of the prize in regard to mode of selection of the candidates, should occasion demand in future years.

## AN AUTO-ASEPTIC THERMOMETER CASE.

At a recent meeting of the Association for the Prevention of Tuberculosis, in Washington, D. C., Mr. Emile Berliner presented a simple improvement in tubes or cases for clinical thermometers which makes possible an automatic and at the same time most thorough disinfection of the thermometer after each use.

The improvement consists in a soft rubber or leather washer placed where the top of the tube or case is screwed to its body. This washer seals the case and renders it watertight. Solutions of formaldehyde, carbolic acid, bichloride of mercury, peroxide of hydrogen or other powerful disinfectants are poured into the tube, filling it, say, one half.

When required for use, the thermometer is rinsed off in water, wiped dry, and the temperature is taken; this is repeated afterwards before it is put back into the case. A single shake will then cover the thermometer with the antiseptic fluid and disinfect it.

In using this case the question to be decided is about the kind of antiseptic fluid which should be used. This was brought out in the discussion which followed Mr. Berliner's presentation and which was participated in by Gen. George M. Sternberg, Dr. George M. Kober, Dr. E. C. Schroeder, Dr. G. Lloyd Magruder and Dr. W. C. Gwynn, all of whom agreed upon the undoubted value of Mr. Berliner's conception. Dr. Schroeder favored a 5% carbolic acid solution and Dr. Kober has already undertaken to have experiments made at the Hospital Laboratory of Georgetown University in order to settle the question.

No patent has been taken out on this device.

## MEDICAL MATTERS IN THE PHILIPPINES.

### Leprosy, Beri-beri, Yaws and "606."

With permission, we make the following interesting extracts from a private letter from the Philippines:

"I am just out on a very extensive leper-collecting trip which embraces the entire archipelago and which I hope will result in the transfer to Culion of every known leper in the Philippines. I often wish that you could make another of these trips with me.

"We are having great success with the rice theory as the cause of beri-beri. Since we began the use of unpolished rice the disease has completely disappeared in all public institutions, and similar results have been obtained in Siam and other places where it has been put into effect. You know, of course, that the theory is based upon the fact that the outer portion of the rice grain contains the bulk of the phosphorus and that persons who live on polished rice, which has the outer coating polished away, are deprived of the necessary phosphorus which the human organism demands. It is alleged that beri-beri is nothing more than phosphorus starvation. At Culion alone, the death-rate by eliminating beri-beri dropped from an average of about eighty a month to an average of ten a month, based on the same population.

"You will probably remember the many cases of yaws we saw on the leper trip and particularly the horrible ulcerations and contractions which

we encountered. In the former disease '606' produces almost miraculous cures within a period of ten days, and if the theory is correct that the latter cases are the third stage of yaws, we should get similar results. We will, of course, try this just as soon as a supply of '606' becomes available."

## EXPENDITURES FOR CONSERVATION OF HEALTH.

In a recent address before the City Club of Chicago, Mr. W. A. Evans, health commissioner of that city, presented some data, from statistics of the United States Census Bureau, showing the amount per capita spent in 1908 by American cities for conservation of the public health. Of cities having a population of over 30,000, Cambridge, Mass, made proportionately the highest expenditure for this purpose, 63.6 cents to each inhabitant. Yonkers, N. Y., came next, with 58.1 cents; New York City third, with 54.7; Denver, Colo., fourth, with 48.5, and Boston fifth, with 47.9. On the same rating, Chicago stood at the foot of the list, with a per capita expenditure of only 20.8 cents. This does not mean, however, that Chicago in 1908 had the highest morbidity or mortality rate. The basis on which these figures are computed seems open to obvious delusive conclusions, and it does not follow that the city which ostensibly spends most for so-called health conservation is necessarily the most healthful.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JAN. 14, 1911.

| CITIES. | Reported deaths in each. | Deaths under five years. | CITIES. | Reported deaths in each. | Deaths under five years. |
|---|---|---|---|---|---|
| New York | 1,508 | 373 | Waltham | 7 | 0 |
| Chicago | 720 | 194 | Brookline | 8 | — |
| Philadelphia | — | — | Chicopee | 7 | 2 |
| St. Louis | — | — | Gloucester | — | — |

## SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The annual meeting of the society will be held in Sprague Hall, Medical Library Building, on Monday, Jan. 30, 1911, at 8.15 P.M. Program: "The Clinical and Scientific Significance of Dreams and Dream-Symbolism, with Special Reference to the Work of Freud," Dr. James J. Putnam. "Men, Manners, and Medicine," Dr. Robert M. Green. The annual business meeting will be held at 9 P.M. Members of the Suffolk District Medical Society are cordially invited to attend.

DANIEL F. JONES, M.D., *Secretary*,
195 Beacon St.

THE NORFOLK DISTRICT MEDICAL SOCIETY.—A regular meeting of the society will be held at Masonic Temple, 171 Warren Street, Roxbury, Tuesday, Jan. 31, at 8 o'clock. Telephone Roxbury 2275S. Business. Communications: "Institutional and Non-Institutional Treatment of Inebriety," Irwin H. Neff, M.D. "After-Treatment and the Out-Patient Department," John A. Horgan, M.D. "General Discussion and Emmanuel Methods," Samuel McComb, A.M., D.D. Discussion by H. Lincoln Chase, M.D., Fredrick L. Taylor, M.D. Refreshments after the meeting.

BRADFORD KENT, M.D., *Secretary*,
798 Blue Hill Ave., Dorchester.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.—The spring meeting will be held in Sprague Hall, Medical Library, Boston, on Wednesday, Feb. 1, 1911, at 1 o'clock. The following papers will be read and discussed: 1. "The Function of the Medical Examiner," George Burgess Magrath, M.D., Medical Examiner, of Boston. 2. "Points of Medico-Legal Interest in the Glover Murder Case," George L. West, M.D., Medical Examiner, of Newton. 3. "Oil of Cedar Poisoning," Everett A. Bates, M.D., Medical Examiner, of Springfield. 4. "The Howard Murder Case," Garry de N. Hough, M.D., Medical Examiner, of New Bedford.

OLIVER H. HOWE, M.D., *Recording Secretary*,
Cohasset.

## RECENT DEATHS.

HUTCHINSON, EDWIN DARIUS, M.D., M.M.S.S., died in Westfield, Jan. 19, 1911, aged seventy years.

BLAIR, ARTHUR WALTER, M.D., M.M.S.S., died at Duxbury, Jan. 18, 1911.

DR. NATHANIEL R. CHACE, of Newport, R. I., died in that city, on Jan. 3. He graduated from the Hahnemann Medical College in 1872.

DR. JOHN WOODWARD GOULD, of Newark, N. J., died on Jan. 16, in his seventy-second year. He was graduated from the Albany Medical College in 1860.

DR. CHARLES EDWARD CLARK, of Lynn, Mass., who died last week of heart disease, at Passaic, N. J., was born in Auburn, Me., in 1850. He received the degree of A.B. from Bowdoin in 1871, and that of M.D. from Harvard in 1877. He practised medicine for some time at Lynn, but retired several years ago. He was married last October.

DR. EUGENE P. HICKOK, of Brooklyn, N. Y., died at his country residence, on Lake George, on Jan. 19, at the age of fifty-one years. He was a native of Owatonna, Minn., and was educated at Carlton College. He commenced his medical studies at Ann Arbor, and was graduated from the [Long Island Medical College in 1890. At the time of his death he was attending physician to the Lutheran Hospital, Brooklyn.

DR. WILLIAM S. ELY, one of the most prominent physicians of Rochester, N. Y., died on Jan. 15, after a long illness. He was graduated from the College of Physicians and Surgeons, New York, 1867, and for about forty years had been attending physician to the City Hospital of Rochester. During the Civil War he served as an army surgeon, and a few years ago was President of the Medical Society of the State of New York.

DR. EDWARD DARIUS HUTCHINSON, who died last week of pneumonia, at Westfield, Mass., was born in Livermore, Me., on Sept. 20, 1840. At the outbreak of the Civil War he enlisted in the Seventh Massachusetts Regiment and served with that command until March, 1863, when he was discharged for disability. Going to Cortland, N. Y., he engaged in the boot and shoe business and was married there in 1866. In 1867 he went to Bridgewater, Mass., and studied dentistry there for a time, but later entered the University of Vermont, from which he received the degree of M.D. in 1875. For some time he practised medicine at Huntington, Mass., but in 1876 settled at Westfield. For many years he had been on the consulting staff of the Noble Hospital in that city. He was a Fellow of The Massachusetts Medical Society. He is survived by his widow and by three brothers.

## REFLEX DISTURBANCES.

PAPERS PRESENTED AT THE MEETING OF THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK, MONDAY, DEC. 19, 1910.

### I. REFLEXES IN SURGICAL DIAGNOSIS.

BY ROBERT T. MORRIS, M.D.,

*Professor of Surgery at the New York Post-Graduate Medical School and Hospital.*

WE are past the pivotal point and have reached the law of diminishing returns in diagnosis, when specialism has arrived at the point where the neurologist fails to recognise organic causes for surgical symptoms, and when, on the other hand, the surgeon fails to note general conditions which give symptoms simulating those of surgical conditions.

The time has arrived when we must go back to the development of the general diagnostician as the most important factor in the medicine of to-day.

Take, for example, ulcer of the stomach. I have, in common with other surgeons, cases from all parts of the country sent for operation, that are not cases for operation at all. Some of the cases sent in with the diagnosis of ulcer of the stomach are really cases of that sort. Others are cases of gallstones, or bile tract adhesions, or fibroid degeneration of the appendix, or early pregnancy, with symptoms like those of some cases of ulcer of the stomach. Others are cases of eyestrain in which the chief demonstration is in the gastric region. Still others are cases of psychosis, or psychoneurosis, with symptoms demonstrated in the gastric region.

As another example of a group of cases often representing reflex disturbance, let us take flexions of the uterus. A very small percentage is due to actual anatomic or embryonic defect, and needing surgical attention. Another percentage of flexions of the uterus is dependent upon spasm which belongs to the neurotic habit, and requires little or no local surgery. The largest group of all seems to include those cases of spasmodic flexion which occur in response to some peripheral irritation at a distance, and which may be distinctly surgical so far as demanding relief from the distant peripheral irritation is concerned. These patients in times past, and even at the present time, are all in danger of being treated indiscriminately for the local condition of flexion, without regard for the underlying causative factors, for a condition which generally belongs in the same class with a sneeze. Reduced to its simplest terms as a proposition, there is not much real difference between a sneeze and an ordinary flexion of the uterus.

Many cases of neuralgia, treated medically, belong distinctly in the surgical class. We often enough have lumbago, or neuralgia of the sciatic nerve, due to an enlarged prostate gland, distended seminal vesicles, pelvic adhesions and to septic or mechanical disturbance of the uterus and adnexa. Cases of trigeminal neuralgia are commonly treated on medical diagnosis only, and patients often tell me they have not even been questioned, by neurologists of standing, relative to peripheral irritations. I recently operated upon a patient who had suffered intensely from trigeminal neuralgia, and who had been given alcohol injections by a most competent surgeon interested in that subject, but who had not examined her pelvis at all. So intense was her suffering that at the time of the last alcohol injection she prepared a fatal dose of morphine in a glass of water to be taken just before her anesthesia. She wished to commit suicide, but to avoid disgrace to the family by having it appear that she had died from the influence of the anesthesia. The reason why she did not take the dose was because at the last moment the anesthetist refused to allow her the glass of water. When she came under my care a little later, and a large ovarian cyst was removed, her neuralgia disappeared promptly, excepting for an occasional twinge of the supra-orbital nerve at times when the barometer is low. In this case the ovarian cyst was the precipitating factor in a patient no doubt predisposed to trigeminal neuralgia.

In another case, a somewhat illiterate old lady with a competence allowing her to consult good authorities informed me that she had suffered terribly from "neurology," as she put it, and I found her statement quite true at its literal value. In this case I excised a portion of the inferior dental nerve, giving relief for about a year. On the return of the neuralgia I did what should have been done in the first place, — sent her to a competent ophthalmologist to determine if eyestrain could be a peripheral factor in the case. He has apparently cured her neuralgia permanently by correcting eye muscle imbalance.

The subject as a whole is too large for presentation in this short paper, and I have brought forward salient points as they appear to the surgeon for purposes of discussion.

In closing the discussion, Dr. Morris said that on boiling down the remarks of various speakers he had obtained two chief lumps of nutritious material. One was from Dr. Fisher, who said that the trouble with the profession lay in confusing the terms "reflex" and "referred." Dr. Morris said that he himself had confused the terms and had used the term "reflex symptoms" in place of "referred symptoms," and he felt that perhaps confusing nomenclature represented the crux of the difference of opinion between surgeons and neurologists, although patients sent in for operation had often not been questioned at all relative to peripheral irritators. The other lump was the fact impressed by Dr. Woodward that the diagnostician needs to be a good editor. He must get together all sorts of testimony from various sources, and then edit the testimony.

## II. DISTURBANCES DEPENDENT ON EYE-STRAIN.

BY ELLICE M. ALGER, M.D.,

*Adjunct Professor of Ophthalmology, New York Post-Graduate Medical School.*

IT is an old saying that the eye is but an expanded portion of the brain, but we seldom stop to think how complicated sight is or how large a portion of the brain is devoted to its perfection. Not only must the retina be exquisitely sensitive to light, but the refractive media must be so calculated that exact images may be formed on that retina. Furthermore, that perfect image must be formed on one particular spot in the retina of each eye, and the brain must combine the two sensations in order to form the visual judgments which we call seeing. The refractive media must be so capable of change that the retinal image may be kept distinct whether the object be far or near, and the muscles of the eyes so coördinated that no matter where we look, both maculæ may be trained constantly on the object of regard. This clearness of vision and coördination of the two eyes is secured by the joint action of fourteen separate muscles. So necessary and so difficult is the function of vision that four of the twelve great cranial nerves are devoted exclusively to it. Every abnormality of nerve or muscle, no matter how small, either throws the visual machinery entirely out of gear or makes the task of coördination more difficult. When we stop to think that most of us use our eyes almost constantly during our waking period, and that many tasks involve a continuous strain for hours at a time, we begin to understand why vision necessitates expenditures of nerve and muscle energy beyond any other function. And when we further consider the large area of brain devoted to vision, and the very close relationship anatomically between the visual centers and other centers, it need not seem strange that what we rather loosely term eyestrain may exercise a profound and varied influence on those other functions.

We say that a patient is suffering from eyestrain when his eyes are compelled to do work which is beyond their physiological capacity. Unfortunately we have no exact standards for measuring this capacity, only a standard of averages. We know, for instance, that the average patient can read letters of a given size at a given distance, but we find many whose acuteness of vision is far beyond the average. In the same way, we have an average ability to focus near objects which is greatest in youth and diminishes regularly with age, but this power varies enormously even in individuals of the same age.

We are still worse off when it comes to measuring the equally important element of endurance. Just as the strongest man is seldom the most enduring, so the optically perfect eye may be absolutely incapable of enduring continuous hard work.

It is, therefore, perfectly possible to strain even normal healthy eyes by overuse, especially under unfavorable conditions and in lowered health, but the chief strain comes from the efforts of the abnormal eye to compensate for optical defects by increased muscular exertion. A patient may have hyperopia or astigmatism or a latent squint, but if he can compensate for them easily they can hardly be considered pathological, but if this compensation requires an undue expenditure of energy, whether nervous or muscular, eyestrain may be said to be present.

We have, therefore, to deal in each case with an individual problem, and the determination of the exact point where the physiological passes into the pathological depends not only on a proper estimate of any optical defects present but also on a careful consideration of the patient himself, his age, his health, his temperament and the conditions under which his eyes are generally used. It must always be borne in mind that eyestrain is not primarily due to the optical defects themselves, but rather results from the fatigue of overcoming them. Paradoxical as it may seem, therefore, eyestrain is much more apt to accompany good vision than poor. The patient who by straining can see distinctly is under a constant temptation to strain and is much more apt to manifest symptoms than one who has found that he cannot see well no matter how hard he may try. I have seen more than one failure to relieve eyestrain because the chief attention was paid to the bad eye which the patient did not use, while the symptoms came from the good one which he was overusing.

There are at least three distinct types of fatigue symptom, the muscular, the nervous and the psychic. First and most common are the symptoms which are purely muscular. The ciliary muscle, for instance, when tired, does not act smoothly, but overcontracts and overrelaxes, so that vision may be at one instant sharp and clear and the next very indistinct. In the same way fatigue of an extrinsic muscle may cause diplopia. This type of fatigue also causes pain localized in the eyes themselves, but both fatigue and pain may be reflected back along the nerves of sensation and cause sleepiness or depression or headache or neuralgia. In the effort to supply additional stimulation to tired ocular muscles other muscles whose centers adjoin are stimulated and we commonly see screwing of the brows and lids, and less commonly spasmodic contraction of muscles of the face and neck. When this excessive innervation can no longer be maintained, not only does vision fail for the time, but the individual is subject to all the consequences which extreme fatigue of any kind produce on him. Until he has had time to recuperate his stock of nerve power, he may be unable to keep awake or he may be too tired to sleep. He may be too tired to eat or may be entirely unable to digest the food he has eaten. And so on. Just how far we can go in this direction we cannot tell definitely because individual variations are so great, but there seems to be no question that the eyestrain compelled by continuous close work, for instance, may in susceptible individuals develop many motor or secretory anomalies.

Then we must not forget the psychic side of the question. The patient with an astigmatism, for instance, sees all objects more or less distorted and is under the constant necessity of performing a series of mental judgments as to the size and shape of objects. Instead of reading word by word or even phrase by phrase, as most of us do, he often has to read letter by letter. Like a proof reader, he has to devote so close a concentration on the form that the meaning escapes him. Every one now admits this as an important factor in the problem of the backward school child, but it is equally applicable to many an adult who is stupid or apathetic or irritable or easily exhausted. Unless he recuperates nerve and muscle energy very rapidly he is on the verge of nervous exhaustion all the time. The relationship between eyestrain and some of the functional nervous conditions has never been properly studied and would well repay investigation.

In demonstration of this theory of eyestrain we cannot expect the absolute proof that we require in an organic disease of germ origin. To be sure, we can create some of the commoner conditions, such as headache, by creating with glasses an artificial eyestrain; but we often fail because of the enormous variations in the individual's susceptibility to strain and his ability to compensate for it. Even the effects of the same strain on the same individual will vary from time to time with his bodily vigor and the number of other demands on his muscular and nervous energy. For instance, I present several pairs of glasses which will create in you certain types of strain, but they will not affect you all alike and perhaps many of you not at all; but even a momentary use of them will give you an idea of the predicament of the individual who has to cope with this strain throughout his waking hours. All the evidence is, therefore, clinical and as such must be very closely scrutinized. A whole series of cases in which relief of definite symptoms, such as headache, followed correction of eyestrain would be generally accepted as showing a relationship between the two. Even a single case in which definite symptoms are relieved by eyeglasses and recur when they are left off would be worthy of note if we could more definitely exclude the therapeutic influence of suggestion. This possibility should never be forgotten, especially in the large class of neurasthenics and hysterics. Examination of the eyes suggests to them a novel and hopeful explanation of their condition, and, with the mental and physical effects of cycloplegia and the routine of impressive and mysterious instruments is capable of producing a very powerful type of suggestive therapeutics. In no other way can we account for the occasional happy effects of glasses which through some blunder actually increase the strain they were intended to lessen.

I have given you a very brief explanation of the theory of eyestrain; let me now suggest with equal brevity a few of its very numerous practical applications. There are, of course, to the close observer many external indications of eyestrain, such as blinking and screwing of the lids, the formation of abnormal wrinkles, the elevation or depression of an eyebrow, the holding the head in abnormal positions, as well as many chronic inflammatory conditions of the lids and conjunctiva. But there are many other symptoms which result sometimes from eyestrain and sometimes from other sources of reflex irritation, and we can make a diagnosis only by a process of exclusion, taking the most probable cause first. For instance, take the symptom headache. It is generally admitted to-day that eyestrain is the commonest cause of chronic headache, and yet there are innumerable other possible causes. Examination of the eyes should be one of the first procedures because the eye is such a probable cause and because it takes so short a time to exclude it. It can easily be determined in a few days' time not by finding an optical error, for that can always be found and proves nothing, but by the actual therapeutic result of treatment. It would take a much longer time to find out whether the headache came from a pelvic abnormality or an autotoxemia. It may also be a question of expediency. Many people, for instance, have headache after an illness which has impaired temporarily their vitality, but the ache itself may actually occur from strain of a weak ciliary muscle and we can relieve this strain by glasses in very much less time than we can restore the muscular strength.

I wish also to draw your attention to a number of common conditions in which the eyes are not by any means undisputed factors. For instance, in migraine or sick headache the usual teaching is that the eyes are not factors at all, the symptoms being due to vascular changes in the brain of an individual who inherits an unstable nervous equilibrium and is also guilty of autotoxemia. Read any of the standard textbooks and you will be struck with the fact that the writers have little to offer and are profoundly pessimistic, both as to patient and prognosis.

Examination of the eyes is almost the only hopeful possibility. Every one of the individual symptoms of migraine are seen over and over again in eyestrain cases, and, so far as my own experience goes, and it includes a great many cases of typical migraine, relief is the rule and not the exception. I do not say they are cured, for I presume the hereditary instability is still there, but some of them never have any attacks at all and others only an occasional one and all without having to practice any special self-denial either in work or play. I am well aware that many ophthalmologists disbelieve entirely in the association of migraine and eyestrain, and there are, of course, many cases in which other factors predominate, but in my own experience complete failures have been surprisingly few.

There is another large class of patients in which I think functional insufficiency of the eyes plays a far more important part than is generally believed. We apply the indefinite term "neurasthenia" to a multitude of people whose chief symptoms are muscular and nervous irritability

and fatigue manifested in many ways. There is no question at all that in many of them eye symptoms exist which are distinctly secondary to the neurasthenia; symptoms which can be relieved gradually by improvement of the general health, but which disappear much more rapidly when intelligent eye treatment is added. But the question is much wider than this. Some of these neurasthenics are doubtless born unstable, but many more have instability forced upon them. In many of them eyestrain simply plays the rôle of the last straw, but in many others it may be one of the basal conditions. Be that as it may, there is no question that an intelligent eye treatment will relieve many of the neurasthenic's most distressing symptoms, though I am also aware that some of this benefit is the result of suggestion. I am sure that in these cases which are very often simple fatigue neuroses we spend all too much time in hunting for fatigue fields, color inversions, and the like, and all too little on far more essential details.

When a woman of any age between thirty-five and fifty comes to us complaining that she has headaches, that she is tired and nervous and depressed, it immediately occurs to us, as it already has to her, that this is the period popularly called the change of life when such sensations must be expected and endured as best they may. In men of the same age we speak learnedly of uric acid, gout, intestinal autotoxemia; warn against the pleasures of the table, and perhaps prescribe sour milk. But we should always bear in mind that this same age in both sexes marks the onset of the great eye change, presbyopia, which simply means that even the normal individual's accommodative power is approaching the vanishing point, and that ordinary daily tasks are performed with great though perhaps unconscious effort. Many of the symptoms so common at this age we should recognize at once as possibly being due to eyestrain. If time permitted I could give you clinical reasons for believing that the eyes may be the cause, in some cases at least, of functional anomalies of the stomach and intestines, such as nausea and vomiting, of occasional cases of neuralgia and reflex abdominal pain, of some cases of wry neck and spinal curvature of the lateral type. It would be interesting also to say something of differential diagnosis and methods of treatment, but this, too, time forbids. Suffice it to say that success depends on at least three factors — the skill of the physician in making his provisional diagnosis, the skill of the oculist in correcting errors, and upon the intelligence and tractability of the patient. In all three there is room for infinite advancement.

## III. REFLEXES AND REFLEX NEUROSES FROM THE UPPER AIR TRACT. (INCLUDING THE NOSE AND PHARYNX.)

BY W. SOHIER BRYANT, A.M., M.D., NEW YORK.

NORMAL automatic reaction to stimulation constitutes a reflex. The impulse enters by a centripetal route and passes out centrifugally. Sneezing and coughing are normal reflex actions.

Abnormal automatic reaction to stimulation constitutes a reflex neurosis, or, in other words, a pathological reflex. The term "reflex neurosis" includes all circulatory, secretory and trophic reflex disturbances and referred sensations, sensory and motor.

More than two hundred and forty-seven different reflexes and reflex neurotic symptoms have been recorded as emanating from some part of the upper air tract, which includes forty-one distinct anatomical structures — the nose with its sixteen parts, the ten parts of the sinuses, the uvula, the velum palati on both sides, the tonsils, both sides of the pharyngeal tonsil, the pharyngeal bursa, the two sides of the fossa of Rosenmüller, two vaults, the two lateral tracks above and below the palate. From any of these parts reflex disturbances may originate. The above-mentioned reflex manifestations are due to at least two causes — local inflammatory or structural conditions. Each stimulation may travel over at least two distinct nerve routes.

Multiplying these two hundred and forty-seven symptoms by ten of the anatomical structures (or approximately a quarter of the number of parts), by the two causes, and by two nerve routes, — $247 \times 10 \times 2 \times 2$, — as a conservative estimate we find 9,880 different manifestations from the upper air tract. The reflexes and reflex neurotic symptoms from the nose alone number more than two hundred and twenty, and these effects of a common stimulation act in twenty-four different anatomical groups — the nose itself, the ear, the eye, brain, the head in general, the pharynx, larynx, trachea, esophagus, neck, heart, lungs, parieties of the thorax and abdomen, the stomach, intestines, gall bladder, sexual organs, the genito-urinary organs, integument, the muscular and nervous systems in general, the excretory and internal secretory glands, and the circulation.

The cause of the reflex neurosis is a diseased condition of one or more parts of the nerve structures through which the stimulus passes. Reflex neuroses in general may be divided into two large groups, simple and complex.

1. The group of simple reflex neuroses includes all forms of exaggerated reaction to normal or non-pathological stimulation. The paroxysmal sneeze produced by smelling a flower, the cough induced by inhaling fresh air, and the vomiting occasioned by an attempt to swallow a hard object, such as a pill — these are simple reflex neuroses.

The distinguishing characteristic of this group is the hyperesthetic condition of the part stimulated, or the abnormally intense reaction to a normal stimulus. Reflex neuroses do not, therefore, occur in the normal individual, for the primary condition of hyperesthesia in the part stimulated is not present. Hay fever, rose cold, the paroxysmal cough and sneeze are typical examples of simple reflex neuroses from the upper air tract.

2. The group of complex reflex neuroses includes all those symptoms produced by abnormal stimuli, by hyperesthesia of the nerve endings and by disease in the nerve tract and nerve

centers through which the stimulation passes. A neurosis may be produced by any one or all of these conditions in combination; but, owing to the complex and variable nature of the components, it is not possible to reproduce the complex reflex neuroses uniformly by experiment. Asthma, asthenopia, many forms of headache, epilepsy and aprosexia are a few of the many complex symptoms that may originate from some part of the upper air tract. Typical examples are:

(*a*) Headache or face-ache excited by intranasal pressure. The weakened condition of the nerve center through which the impulse travels causes the abnormal stimulation to be referred by irradiation to a healthy area.

(*b*) An asthmatic paroxysm caused by titillation of the nasopharynx with a cotton applicator. This abnormal stimulation of a hypersensitive area causes a violent reaction in the pulmonary apparatus on account of the pathological condition of the nerve centers.

(*c*) An epileptic seizure induced by intranasal pressure with a probe. Here the slight, abnormal stimulus causes a violent psychomotor-sensory paroxysm, which is produced because of the pathological condition of the nerve centers.

Other reflex neuroses, such as cardiac and uterine pains, the demonstration of which is more difficult, may also be attributed to the upper air tract.

*Etiology.* — Simple reflex neuroses, those of the first group, are caused by repeated or prolonged stimulation carried to a point of nervous exhaustion which produces hyperesthesia. Hyperesthesia is the cumulative result of the contact of intranasal surfaces and of irritating dust, vitiated air, too great and too rapid changes in the humidity and temperature of respired air.

Complex reflex neuroses, those of the second group, depend upon structural and peripheral changes which cause an abnormal degree of nerve stimulation. For example, a hypertrophic condition of the nasal mucosa, together with a state of lessened resistance of the nerve centers, as well as a diseased condition of the nerve path, leads to pathological reflex action. A neurotic tendency is usually the fundamental, predisposing cause.

*Diagnosis.* — Simple reflex neuroses can be diagnosed by experimentally inducing a paroxysm. This is done by carefully stimulating every suspected hypersensitive part with a cotton applicator until the active one is discovered and the reflex phenomenon is produced. If this positive method does not determine the diagnosis, a negative one may be employed. Cocainization of hyperesthetic areas during a reflex paroxysm will arrest the attack and establish the diagnosis.

In complex cases, as a rule, a paroxysm cannot be induced experimentally. If in such cases the cocainization of hyperesthetic areas arrests the paroxysm, the origin of the attack is indicated. But if the attack is not arrested in this way, diagnosis can be determined only through the treatment of local abnormalities. When these have been corrected and there is no recurrence of the paroxysm, the probability is that the character of the attack was reflex, and it is safe to assume that the reflex neurosis has been arrested by the removal of the peripheral factor.

In cases of neuroses which do not yield to other treatment, and the origin of which has not been found, a diagnosis of reflex action from the upper air tract is justifiable, and treatment of the manifestation should be undertaken on that basis.

The differential diagnosis between reflex neuroses and toxic effects from infection of the upper air tract is sometimes extremely difficult to determine because of the similarity in the character of the irritations. By removing the peripheral irritation, the seat of infection may also be removed. I believe we are justified in calling the phenomenon a "reflex neurosis" when the removal of pressure under local anesthesia immediately checks a paroxysm, because the excision of the toxic focus cannot produce so rapid an effect.

*Treatment.* — Elimination of the peripheral exciting cause, i. e., the hyperesthetic area, must be the first consideration in treatment, because the nerve path is less amenable and the fundamental neurotic tendency is still more resistant to treatment. On the other hand, it is always possible to remove the peripheral factor. In acute conditions, the hyperesthesia yields to soothing, depletent applications. In chronic conditions, resection is preferable to cauterization because the good effects are permanent by the first method and may not always be obtained by the second.

*Prognosis.* — The prognosis for permanent relief from attacks is good when the peripheral factor has been removed. (In very nervous, neurotic patients, similar or different reflex neuroses occasionally appear from other anatomical parts. These symptoms in turn will yield to appropriate treatment.)

*The nose, the peripheral organ of the sympathetic nervous system.* — Reflexes and reflex neuroses emanating from the upper air tract are of greater variety and importance than those from any other region. This is explained by the fact that the nerve supply of the upper air tract, and especially that of the nose, is largely sympathetic in character. In 1842, Bidder and Volkmann [1] stated that they had counted in the nose twenty times as many sympathetic nerve fibers as cerebrospinal. The sympathetic nerve supply of the nose is, in fact, more abundant than that of any other superficial organ; hence the response from the nose is fundamentally somatic in character. For all these reasons I believe we are justified in calling the nose the peripheral organ of the sympathetic nervous system.

Compared with other sense organs, the nose, so far as its reflex action is concerned, is of primary importance. Digestive and metabolic disturbances from improper diet have an intense influence upon the organ. Sudden changes from hot and dry to cold, damp air and back again

[1] "Die Selbständigkeit des sympatischen Nervensystems durch anatomische Untersuchungen nachgewiesen," Leipsic.

leave their ill-effects upon the nose. The infected dust, poisonous gases and the smoke of civilized communities are factors that ceaselessly exert a baneful influence upon the nasal mucosa. Mental strain and emotional excitement affect the nose unfavorably. Eyestrain as a cause of reflex neuroses takes a secondary place in comparison with nose-strain: the first is intermittent and voluntary; the latter is constant and involuntary.

The human nose and its nerve supply are in a state of degeneration. Dahl and Müller [2] have shown that in man the sphenopalatine ganglion which largely supplies the nose is a very variable structure. When compared with that of domestic animals it shows marked degeneration. The extraordinary susceptibility of the nose to pathological reflex action is undoubtedly to be attributed to its constant and abnormal irritation as well as to the degenerative and consequently unstable tendency of its nerve supply.

The reflexes and reflex neuroses emanating from the pharynx in number and significance are second only to those arising from the nose. From the following lists a realization will be gained of the great variety and vital importance of reflexes and reflex neurotic symptoms from the upper air tract, including both the nose and the pharynx.

### I. REFLEXES AND REFLEX SYMPTOMS FROM THE PHARYNX.

#### ACTING IN PHARYNX.

*Circulatory:* Congestion of mucosa, closure of pharyngeal mouth of Eustachian tube by congestion of mucosa, anemia of mucosa, opening of pharyngeal mouth of Eustachian tube by anemia of mucosa.

*Trophic and secretory:* Hypersecretion of mucous membrane, hyposecretion of mucous membrane, hyperfluid secretion of mucous membrane, hypofluid secretion of mucous membrane, hyperfibrous secretion of mucous membrane, hypertrophy of mucosa, atrophic changes of mucosa, hypertrophy of pharyngeal pituitary, atrophy of pharyngeal pituitary, stimulation of pharyngeal pituitary, inhibition of pharyngeal pituitary.

*Motor:* Parestaltic movement of pharyngeal muscles (swallowing), antiparestaltic movement of pharyngeal muscles (regurgitation), muscular closure of pharyngeal mouth of Eustachian tube, muscular opening of pharyngeal mouth of Eustachian tube, contraction of palate muscles, spasmodic movement of palate muscles, contraction of pharyngeal muscles, spasmodic movement of pharyngeal muscles, spasm of the glottis.

#### ACTING IN NOSE.

*Circulatory:* Congestion of mucosa, sagging turbinates, swelling of turbinates from congestion and stoppage of nose, contraction of lumen from engorgement of mucous lining, obstructed nasal breathing, edema of mucous lining, anemia of mucosa, contraction of turbinates, shrinkage of turbinates from anemia of nose, dilatation of lumen of nasal fossæ from shrinkage of mucous lining.

*Sensory:* Feeling of pressure in sinuses from intranasal pressure, pains referred to sinuses, nose-ache.

*Trophic and secretory:* Hypersecretion of nasal mucosa, rhinorrhea, hyposecretion of nasal mucosa, dryness of mucosa, hyperfluid secretion, hyperviscid secretion, hypermembranous secretion, vasomotor rhinitis, hay fever, rose cold, hypertrophy of mucosa, atrophy of mucosa.

[2] "Die Beteilung des sympatischen Nervensystems an der Kopfinnervation." Deut. Arch. für klin. Med., Leipsic, 1910, pp. 49–107.

#### ACTING IN EAR.

*Circulatory:* Congestion, anemia, occlusion of Eustachian tube.

*Sensory:* Pain in ear, pain in front of ear, pain in mastoid region, tinnitus (many kinds), vertigo.

*Motor:* Twitching sensation in ear, tonic and clonic contraction of internal muscles of ear.

*Trophic:* Hypertrophic changes, atrophic changes, otosclerosis, catarrhal conditions.

#### ACTING IN EYE.

Lacrimation, eye-ache, soreness of orbit, dilatation of pupils, contraction of pupils, asymmetry of pupils, errors of accommodation, ciliary spasm, functional disturbances of retina from dilatation of uvea, extreme vascularity of ciliary body causing disturbances of pigment layer of retina, asthenopia (weak vision).

#### ACTING IN BRAIN.

*Circulatory:* Congestion, anemia.

*Functional:* Nightmare, failure of memory, diminution of psychic energy, aprosexia, unconsciousness.

#### ACTING IN HEAD.

*Sensory:* Forehead headache, temporal headache, occipital headache, vertex headache, stuffy headache, chronic headache, face-ache, trifacial neuralgia, toothache (upper), toothache (lower).

*Trophic and secretory:* Nausea, hypertrophy of cerebral pituitary, atrophy of cerebral pituitary, stimulation of cerebral pituitary, inhibition of cerebral pituitary, trophic disturbances of scalp (alopecia).

#### ACTING IN THROAT AND NECK.

*Larynx:* Weak voice, hoarseness, aphonia, soreness of larynx and trachea, discomfort referred to anterior region of larynx, congestion of larynx, partial paralysis of larynx, laryngeal spasm, laryngeal vertigo.

*Neck:* Muscular tenderness, muscular pains, pain behind ramus of jaw, pain under jaw, pain extending down neck along sternocleido-mastoid, throatache, discomfort below hyoid bone, discomfort referred to anterior border of sternocleido-mastoid, nerve tenderness, cervical neuralgia, torticollis, rigidity of head and neck, spasmodic movement of head and neck, spastic torticollis, globus, choking sensations.

*Thyroid:* Hyperthyroidism, exophthalmic goitre, hypothyroidism, myxedema, hypertrophy, atrophy.

*Thymus:* Stimulation of thymus, inhibition of thymus, hypertrophy of thymus, atrophy of thymus.

*Carotid gland:* Stimulation of carotid, inhibition of carotid, hypertrophy of carotid, atrophy of carotid.

*Esophagus:* Aerophagia.

#### ACTING IN THORAX.

*Heart:* Rapid pulse, tachycardia, irregular heart action, intermittent pulse, cardialgia.

*Lungs:* Catarrh of air passages, bronchitis, asthma, forced inspiration.

*Parieties:* Muscular pains, pain along sternum, pain between scapulæ, intercostal neuralgia, other thoracic neuralgias.

#### ACTING IN ABDOMEN AND PELVIS.

*Stomach and intestines:* Gastric pain, digestive disturbances, gastric crisis in smokers, gastro-intestinal disturbances, vomiting.

*Parieties:* Muscular pains, lumbar pains, neuralgia.

#### GENERAL REFLEX ACTION.

*Co-ordinate:* Acceleration of respiration, retardation of respiration, cough, paroxysmal cough, sneeze, paroxysmal sneeze.

*General:* Habit chorea, pains in bones, "rheumatic" pain and tenderness, sciatica.

### II. REFLEXES AND REFLEX SYMPTOMS FROM THE NOSE.

#### ACTING IN NOSE.

*Circulatory:* Congestion of mucosa, sagging turbinates, contraction of lumen from engorgement of mucous

lining, obstructed nasal breathing, edema of mucous lining, anemia of mucosa, contraction of turbinates, dilatation of lumen of nasal fossæ by shrinkage of mucous lining.

*Sensory:* Feeling of pressure in sinuses from intranasal pressure, pains referred to sinuses, nose-ache.

*Trophic and secretory:* Hypersecretion of nasal mucosa, rhinorrhea, hyposecretion of nasal mucosa, dryness of mucosa, hyperfluid secretion, hyperviscid secretion, hypermembranous secretion, vasomotor rhinitis, hay fever, rose cold, hypertrophy of mucosa, atrophy of mucosa.

### Acting in Ear.

*Circulatory:* Congestion, anemia.

*Sensory:* Earache, tinnitus (many kinds), tickling in ear, sensation of fullness and pressure in ear, sensation of weight in ear, vertigo.

*Motor:* Twitching sensations in ear, tonic and clonic contraction of internal muscles of ear.

*Trophic:* Hypertrophic changes of middle-ear tract, atrophic changes of middle-ear tract, otosclerosis, catarrhal condition of middle-ear tract, catarrh of Eustachian tube.

### Acting in Eye.

Lacrimation, eye-ache, eyestrain, photophobia, ambiopia or diplopia, asthenopia, amaurosis, contraction of visual field, scotoma scintillans.

*Lids:* Chalazion, edema of lids, hyperemia of lids, itching of lids.

*Conjunctiva:* Hyperemia of conjunctiva, edema of conjunctiva, chemosis, itching of inner canthus, catarrhal condition, altered secretion of conjunctiva.

*Cornea:* Erosion of superficial layer of cornea.

*Pupils, etc.:* Contraction of pupils, dilatation of pupils, asymmetry of pupils.

*Retina, etc.:* Distention of uvea leading to disturbances in pigment layer, dilatation of uvea and vascularity of ciliary body, glaucoma, choked disk.

*Muscles:* Blepharospasm, rhythmic blepharospasm, ptosis, external strabismus, internal strabismus, ophthalmoplegia, errors of accommodation, contraction of ciliary muscles, paresis of ciliary muscles.

### Acting in Brain.

*Circulatory:* Congestion, anemia.

*Sensory:* Feeling of seasickness, dazed feeling from nasal pressure, feeling of pressure in brain.

*Functional:* Insomnia, nightmare, uncontrollable somnolence, epilepsy, diminution of psychic energy, failure of memory, inability to concentrate, aprosexia, psychic depression, uncontrollable melancholy.

### Acting in Head.

*Circulatory:* Redness of cheeks, paleness of cheeks, erythema.

*Sensory:* Feeling of pressure in head from sinus or nasal pressure, pain and tenderness in nasolabial area, pain and superficial tenderness over frontonasal and midorbital region, symptoms resembling sinusitis from intranasal pressure, muscular pains, face-ache, toothache (upper), toothache (lower), forehead headache, temporal headache, occipital headache, vertex headache, chronic headache, trifacial neuralgia, tic douloureaux, headache up to hemicrania, hemicrania, migraine.

*Motor:* Spasmodic movement of facial muscles.

*Trophic:* Appetite and hunger, saliva running, nausea, stimulation of cerebral pituitary, inhibition of cerebral pituitary, hyperidrosis of face, trophic disturbances of scalp (alopecia).

### Acting in Throat and Neck.

*Pharynx:* Congestion of pharynx, anemia of pharynx, tickling of palate, tickling of pharynx, hypersecretion, hyperfluid secretion, hypofluid secretion, hyposecretion of mucous membrane, spasmodic movement of pharyngeal muscles, spasmodic movement of palate muscles, stimulation of pharyngeal pituitary, inhibition of pharyngeal pituitary.

*Larynx and trachea:* Weak voice, hoarseness, aphonia, partial paralysis of larynx, laryngeal spasm, catarrhal laryngitis.

*Neck:* Spasmodic movement of head and neck, rigidity of nape of neck, muscular pains, neuralgia, throatache.

*Thyroid:* Hyperthyroidism, exophthalmic goitre, hypothyroidism, myxedema, hypertrophy of thyroid, atrophy of thyroid.

*Thymus:* Stimulation of thymus, inhibition of thymus, hypertrophy of thymus, atrophy of thymus.

*Œsophagus:* Aerophagia.

### Acting in Thorax.

*Heart:* Rapid pulse, tachycardia, irregular heart action, intermittent pulse, cardialgia, hypertension of arteries, hypotension of arteries, angina pectoris, instantaneous arrest of heart action, arrest of heart action (death) from anesthesia of nose, especially in status lymphaticus.

*Lungs:* Catarrh of air passages, bronchitis, contraction of bronchial muscles, relaxation of bronchial muscles, asthma, spasmodic expiration, arrest of respiration, arrest of respiration in expiration.

*Parieties:* Muscular pains, pain along sternum, pain between scapulæ, neuralgias (intercostal and others).

### Acting in Abdomen and Pelvis.

*Gastric and epigastric:* Gallstone colic pain without passage of stones, gastric neuroses, gastro-intestinal neuroses, simulation of gastric ulcer, gastralgia, vomiting.

*Intestines:* Pain in cecal region, mucomembranous colitis.

*Sexual organs:* Sexual excitement, pain in genitals, painful menstruation, abdominal menstrual pains, sacral menstrual pains, neuralgic stomachache of menstruation, menstral pain between scapulæ, dysmenorrhea, menorrhagia, pregnancy following clearance of nose, severe vomiting of pregnancy (controlled by nasal manipulation), contraction of uterus, labor pains induced through nasal manipulation, control of true labor pains by means of nose, abortion produced through nasal manipulation.

*Genito-urinary organs:* The following symptoms are either produced or controlled by the nose — enuresis nocturna, pain in renal region.

*Parieties:* The following symptoms are either produced or controlled by the nose — pain in regions innervated by lower spinal nerves, muscular pains, lumbar pains, pain in sacrum, pain in lower abdomen.

### General Reflex Action.

*Co-ordinate:* Acceleration of respiration, retardation of respiration, cough, paroxysmal cough, sneeze, paroxysmal sneeze, hiccough.

### General.

*Integument:* Urticaria, erythema, edema.

*Circulation:* Chilly sensations, feverish sensations, contraction of peripheral blood vessels, dilatation of peripheral blood vessels.

*Muscles:* Chorea.

*Nerves:* Neuralgias and sciaticas, "rheumatic" pain and tenderness.

*Glands:* Excessive perspiration.

## IV. REFLEX DISTURBANCES REFERABLE TO THE EAR.

BY JOHN RANDOLPH PAGE, M.D.,

*Assistant Attending Otologist to the Manhattan Eye, Ear and Throat Hospital, and Babies' Hospital, New York; Adjunct Professor of Otology at the New York Polyclinic Medical School and Hospital.*

This subject is too comprehensive and complicated for me to attempt to cover it in even a superficial way in the time allowed to-night. I will, therefore, consider only a few of the disturbances which are of more or less general interest and practical value.

The contraction of the muscles of the body which occurs when the acoustic nerve is irritated by a loud or unexpected sound is familiar to every one, but it is not generally known that these

reflex contractions can be produced in the newborn and that the extent of the contractions can be made to vary with the intensity of the sound employed. Dizziness, spasm of the respiratory muscles and changes in the heart action can be produced by musical tones, or by certain kinds of noises and sounds, and some neurasthenic people are peculiarly sensitive to irritation of this kind.

More interesting clinically are those disturbances caused by irritation of the nerves which supply the auricle and external auditory canal; namely, the neuralgias and coughs due to irritation of the trifacial, and Arnold's branch of the pneumogastric. A year ago a patient on whom I had performed a radical mastoid operation several years before became afflicted with a "goose cough" which persisted in spite of the treatment administered by her physician. The cough was due to irritation of Arnold's nerve, and it was promptly relieved by the removal of an epithelial crust from the cavity left after the radical operation. Another patient is thrown into an uncontrollable fit of coughing the moment a speculum is introduced into his ear. Such cases are too well known to be more than mentioned.

It is well, however, for the physician to bear them in mind, as a consideration of them may occasionally prove of practical value. Intractable coughs, particularly in children, and neuralgias which have resisted prolonged treatment, are sometimes relieved by the removal of a plug of inspissated wax from the canal.

The disturbances caused by affections of the middle ear are more involved. Reflex psychoses as well as reflex neuroses are met with, and we are startled by the reference of some authors to rather commonplace affections of the middle ear as causes of suicidal mania and profound melancholia. Fortunately such cases are rare. It is true, however, that headache and mental depression are often due to even slight catarrhal affections of the middle ear and Eustachian tube which interfere with the proper ventilation of the inside of the drum.

Pain in acute inflammations of the middle ear is frequently referred more to the temporal region and side of the head than to the ear itself, and it is not uncommon in ear clinics to find patients who have had sound teeth removed because of the pain referred to them from the ear. Even slight inflammations of the middle ear occasionally cause intense facial neuralgia which may be followed by temporary facial paralysis. I recently saw a case of marked edema and neuralgia of the right side of the face associated with slight tinnitus and stuffiness of the right ear. There were no visible signs of inflammation in the middle ear, but relief was afforded by inflation of it and the edema rapidly subsided.

With these neuralgias should be mentioned the cases of herpes oticus which are occasionally seen. Dr. J. Ramsay Hunt reported three cases last winter. He divides them into two groups, one referable to the geniculate ganglion of the seventh nerve and the other to the jugular ganglion of the tenth. They are usually accompanied by intense neuralgia, facial paralysis and auditory symptoms. While in a strict sense neuralgias and referred pains are not reflex, those referable to the ear are mentioned because of their clinical interest.

In passing to the purely reflex disturbances caused by irritation of the internal ear or labyrinth, I can best convey some idea of their number and complex character by saying that every symptom of seasickness in its most aggravated form can be produced by irritation of a normal labyrinth. To be more explicit, the irritation causes a movement of endolymph in the semicircular canals which causes a corresponding movement of the eyes; the surrounding objects seem to swim in the direction of the endolymph movement, and in an effort to overcome the vertigo produced the eyes fix on an object as it passes, and when their limit of movement is attained in that direction they snap back quickly and endeavor to fix themselves again. This peculiar movement of the eyes is known as vestibular nystagmus, and the study of it has proved useful in the diagnosis of labyrinthine disease.

Ewald found by experiment that a movement of endolymph in a semicircular canal is accompanied by a corresponding movement of the eyes in the same direction and in the same plane as that of the canal in which the endolymph moves, and that the snap back or nystagmus is in the opposite direction. The impulse passes from the disturbed endolymph through the vestibular nerve to Deiter's nucleus, thence to the nerves which govern the eye movements and also to the motor neurones of the cord, so not only is there movement of the eyes, but turning of the head and body as well, with staggering and loss of equilibrium. Knowledge of this relationship between the eyes and the endolymph has resulted in the development of the tests for labyrinthine disease now in general use. In cases of chronic suppurative otitis media a fistula in the horizontal semicircular canal can sometimes be diagnosed by compressing air in the middle ear, which causes through the fistula a movement of the endolymph, and a corresponding movement of the eyes. This is known as the fistula test. Bárány's observation of the disturbances produced by the use of heat or cold in the ear lead to his development of the caloric test, which consists in irrigating the ear with either hot or cold water.

When cold water is used in a normal ear a movement of endolymph is produced by convection in the anterior vertical canal downward and towards the ear irrigated, and there is a corresponding nystagmus or quick movement of the eyes to the opposite side; if the irrigation is prolonged, dizziness, nausea and vomiting with profound prostration develops. The same symptoms appear when hot water is used, except that the nystagmus is then towards the side irrigated. Where the water reaches the drum membrane for five minutes or more without the occurrence of any reaction, the labyrinth may be

considered functionless. The reaction occurs much quicker when the drum membrane is perforated or absent, and for this reason it is advisable for people with perforated ear drums to protect their ears before going in swimming. The effect of cold water on the labyrinth in these cases is sometimes very rapid, and the dizziness and loss of equilibrium produced might easily render one helpless in deep water. This is probably the reason why strong swimmers occasionally without warning suddenly utter a cry for help and go down before rescue is possible.

The disturbances caused by the destruction of one or both labyrinths, and the way in which the equilibrium which is at first lost is gradually regained through the sight and muscle senses, is very interesting, but the time is now too short to speak of them.

In conclusion, let me say, with slight exaggeration, that in different cases reported, a plug of impacted cerumen has been known to produce, through its irritation of the external auditory canal, its interference with the pressure equilibrium of the middle ear, and, consequently, that of the labyrinth, nearly every reflex disturbance mentioned to-night, even suicidal mania.

## V. WHAT IS THE MEANING OF REFLEX?

BY EDWARD D. FISHER, M.D., NEW YORK,
*Professor of Mental and Nervous Diseases, the University and Bellevue Hospital Medical College.*

All action is reflex, — breathing, swallowing, in fact, every act unless it has its initiation from the brain in some voluntary purpose. Even this, however, is undoubtedly reflex, as it depends on original primary reflex action. The child when born has had no previous cerebral impression, i. e., those which have entered into its conscious ego, because this has not as yet existed. The cerebral cortex is a blank sheet ready for and by heredity prepared to receive impressions. The child first acts simply reflexly; i. e., a sensory or afferent irritation or impulse is received by a cell group or center which responds through the motor or efferent nerves. The same reflex action can take place in the spinal cord without its recognition by the cerebral cortex or, in other words, by consciousness.

When we speak of reflex conditions we are dealing with an actual state. We must be careful, however, not to misinterpret this. A reflex action is fundamentally the same in all conditions. From the simplest form of protosoal life to the complex mammalia we are always dealing with the afferent or sensory nervous irritation, — the receptive center and its efferent or executive active fibers. In the mammalia repeated sensory impulses become permanently registered in the perceptive centers and become memories, so that many reflex acts are automatic, but they could not have become so unless they had passed through the primary simple process previously referred to. When we try to understand and explain all the conditions involved in reflex action, much must remain indefinite. The sympathetic system has its part to play and modifies the idea of a simple reflex act, as seen in the spinal cord or brain. We understand very little physiologically of the sympathetic system; it is practically *terra incognita*. This is the reason that the theories of Head with regard to our acceptance of them as of practical diagnostic value clinically fail of conviction.

To say that pain or sensory anesthesia in a certain area of the body absolutely indicates a disease of an underlying abdominal organ is difficult to positively acknowledge, if by it we are to definitely decide on an operation. Academically we can discuss the question, or take it up in the laboratory. The active practical worker, however, has to decide on the life and death issue.

Having given the ordinary understanding of the reflex, it would seem apparent that most of the so-called reflex conditions are only referred, that is, the natural conscious perception of a peripheral irritation, whether it be a perception of a color through the medium of the eye, or of hunger through the coating of the stomach. A sneeze can very properly be called reflex, and does not call the (cerebral) consciousness into action any more than the classical experiment on the decapitated frog when irritation of the abdominal wall causes the spinal reflex act of attempting to remove the irritation with the hind leg. That act is, in the true sense, purely reflex. The infinite number of disturbances in the body, whether of pain or other character, resulting from diseased organs, as the nose, eye or the abdominal organs, which specialists in their department of medicine find and call in a vague and indefinite way reflex cannot be called in the true sense of the term reflex, but simply referred. In many instances, in fact, probably most, even this is not the explanation, but rather the solution lies in the fact that we have separate diseased conditions, any of which are sufficient to cause a lowering of the general condition of health and thus permit a functional disturbance of another part of the body to become apparent. This is demonstrated every day when the nasal, ocular or aural specialist, after removing the actual local disease, has to resort to the treatment of the general physical condition, or direct the patient to some one who can, in order to secure the benefit which should result from his side of the case. Were this course more often followed than it is, there would be less complaint on the part of the patient that nothing after all has been accomplished by the generally absolutely necessary treatment of actual morbid conditions of the eye, nose, uterus or other organs.

The word "reflex" has taken such a hold on most specialists that without consideration of the general conditions of health, indeed, often without any study or investigation as to whether the patient has any other faulty condition of the system, they are apt to consider or think they have done all that can be done. The condition now, if not improved, is the patient's own fault. In other words, reflex is now translated, after they have removed all the offensive organs,

turbinated bones, uterus or ovaries, into hysteric or neurasthenic.

I must emphasize here that the neurologist must also be an internist, or as the term should be understood, a general practitioner, or he, in his own peculiar way, will also look on these cases in the same limited one-sided way. Much of this confusion in the practical honest treatment of patients is due to that word "reflex," which relieves everybody from any responsibility and covers errors by a mantle of ignorance.

Let us drop the word and say, when we don't know the cause of the condition, that we do not know, and not placidly sit down and call it "reflex," but in every way open to scientific research work out the cause of the disease. The term "referred" is often explanatory in many cases and then is preferable, but this is not to be accepted in all cases.

Head [1] has given us a theory in regard to reflex pains and anesthesia which he thinks should be held as positive in regard to diagnosis for localizing disease, especially in the abdominal organs. The physiological explanation is beautiful indeed, and from the standpoint of its study, i. e., the academic standpoint, is satisfactory, i. e., a locally diseased organ sends its irritation to the sympathetic system in the cord; the cerebrospinal system, on its part as represented in the spinal cord, sends its notification by expressing itself by anesthesia over the surface of the skin or the organ involved. Clinically it has been demonstrated that when we know by other positive evidence that disease of an organ is present, often no anesthetic or hyperesthetic area manifests itself, so the theory is not of positive diagnostic value. The end result is, therefore, careful examination of every case, looking for what are evident symptoms of varied types, not a single reflex condition.

## VI. REFLEX SYMPTOMS AND DISEASE OF THE NERVOUS SYSTEM.

BY WILLIAM M. LESTYNSKY, M.D.,
*Neurologist to the Lebanon and Harlem Hospitals, New York City.*

THE reflex theory of nervous disease is of very ancient origin. It was based upon mistaken notions about reflex action and has often been confounded with associated disturbances of sensation. Its practical application often implies carelessness or inaccurate observation. We have all occasionally noted the subsidence of nervous symptoms following the removal of adenoids and enlarged tonsils, the correction of refractive and eye muscle defects, the removal of impacted cerumen, the relief of phimosis by circumcision, the cure of posterior urethritis, the repair of lacerated cervix and perineum, the relief of obstructive dysmenorrhea, or the ablation of diseased ovaries and adnexa, etc. But it should always be borne in mind that a co-existing neurotic state is usually intensified and not produced by any of the above-mentioned derangements. While these or similar conditions may cause pain, spasm, convulsion or other distressing nervous symptoms, they have never been known to develop a constitutional neurosis such as neurasthenia, hysteria, hypochondriasis, epilepsy or insanity. It is quite possible, as Dr. Morris has said, that the cause of reflex disturbances of the nervous system is overlooked regularly by diagnosticians. It is much more frequent, however, for organic nervous disease to pass unrecognized, particularly intracranial disease and atypical tabes. Hence, stretching or incision of the anal sphincter for the rectal crises of tabetics, exploratory laparotomy for vomiting associated with brain tumor, extraction of healthy teeth for the relief of tic douloureux, etc.

The term "reflex neurosis" came into existence about thirty years ago, when practical medicine was subdivided. into a number of specialties, different reflexes arising in each circumscribed specialty. It must be deplored that the same old unjustifiable expression is still heard from time to time, thus illustrating the difficulty of overcoming traditional custom.

To those who still adhere to the exploded doctrine of the ancient reflex theory, it may be said that the perpetuation of such a misconception has repeatedly been conclusively demonstrated to be unscientific and irrational. That it is our duty to make every reasonable effort to discover the cause of apparently inexplicable nervous phenomena is axiomatic. Biometric research supplies no practical guide to the individual, and his standardization is impracticable, nay, impossible. A slight physical defect may be significant in one and inconsequential in another, but to interpret (as some have done) such deviation from an arbitrary standard as the reflex cause of disease of the nervous system is a *reductio ad absurdum*.

Among the notable medical fallacies, none have been more prominent and persistent than that of attributing seemingly obscure nervous manifestations either to some reflex irritation originating in the female genitalia, or to so-called imbalance of the ocular muscles. In the majority of instances, the causal relationship cannot be satisfactorily established except in the fanciful minds of those with preconceived notions.

Absolutely authentic cases are extremely rare. In this connection it may be of historical interest to mention that soon after the advent of antiseptic and later aseptic surgical technic, the sacrifice of normal ovaries became extraordinarily and alarmingly frequent. Oöphorectomy was unsuccessfully practiced for the cure of neurasthenia, hysteria, hypochondriasis, epilepsy and insanity. Of course, in many cases such surgical interference was looked upon and condoned as a *dernier ressort*, but the conclusions as to etiology were based upon false premises. Although the pendulum is still swinging, such unwarrantable surgical mutilation is gradually but rapidly coming to a halt.

Some years ago, Dr. George T. Stevens of this city enthusiastically claimed that chorea and epilepsy were reflex conditions resulting from

[1] See Brain, 1906.

heterophoria or imbalance of the ocular muscles. At that time, I was associated with my friend, Dr. David Webster, and the late Drs. E. C. Seguin and Cornelius Agnew, at the Manhattan Eye and Ear Hospital, in studying the condition of the ocular muscles and refraction in patients with various functional nervous disorders. The muscle examinations were carefully made with the phorometer devised by Dr. Stevens and according to his methods, and continued over a period of two years. As the result of my observations at that time, and from subsequent investigation, I have reached the conclusion that muscular anomalies producing latent diplopia and unconscious efforts to maintain binocular single vision are undoubtedly a drain upon the nervous energy, often aggravating if not producing many neurasthenic and psychasthenic phenomena. But I am yet to be convinced that such is the cause of chorea, epilepsy or any other constitutional disease of the nervous system. As to published reports of cases of chorea, epilepsy, insanity, etc., having been cured by the surgical adjustment of ocular muscles, I have no desire to question the judgment or veracity of certain observers, but many of the cases thus reported will not successfully bear critical neurological analysis. To assert that patients have recovered from these neuroses after oöphorectomy, or after the correction of ocular defects, or cauterization of the nasal mucous membrane, urethra, etc., is begging the question, and does not necessarily imply that such affections were of reflex origin. In many cases the alleged rapid (but usually temporary) recovery has been due to suggestion, and the same result may often be accomplished by simpler and safer means. In psychasthenic and impressionable individuals, many so-called reflex symptoms may be initiated or fostered by suggestive physical examinations or injudicious remarks of the attending physician.

The disastrous effects of the reflex theory of nervous disease are quite familiar and require no further demonstration. Yet its misapplication is still more or less prevalent. The unfortunate tendency to ascribe many misunderstood nervous symptoms to so-called reflex causes is due, in a large measure, to the neglect of the majority of physicians to avail themselves of a working knowledge of the fundamental principles of neurology.

## THE INTRAVENOUS USE OF COCAINE. REPORT OF A CASE.

BY PAUL W. HARRISON, M.D., BOSTON.

In the *Berliner Klinischer Wochenschrift*, vol. xlvi, p. 1701, Ritter reports experiments on animals where cocaine in moderate doses (½ gr.) was administered intravenously. This was followed almost immediately by complete general analgesia. There was little or no interference with motor function. The results were so striking as to apparently demand investigation in human beings.

The subject of this experiment during the past three years three times had local anesthesia produced with cocaine, — once of a finger, once for work on teeth, once about a boil on the back of the neck. The analgesia produced at these times was not different in character or duration from that usually seen. There had been no other use of cocaine or allied drugs. This experiment was performed as follows:

Into one of the superficial veins of the back of the hand there was slowly introduced 5 gr. of cocaine in a 2% solution. The introduction of the solution was completed in about thirty minutes. Dizziness and palpitation made it seem wise to stop with this amount. Tests of the patient's condition were made at once and results found to correspond in an incomplete way with those reported for animals.

Cerebration was normal except for a restless inability to keep the mind long on one subject. Motor power was quite unimpaired.

There was marked analgesia everywhere. An incision ½ inch long through the skin, well down into the fat, was made on the anterior surface of the lower leg. This incision could be felt. It caused a mere trifle of pain. Two or three small nerves in the fat were cut. Each caused a slight twinge of pain. Apparently operative procedure might readily have been undertaken with only very moderate discomfort.

Two hours later a similar central incision was made on the opposite side. The sensation of pain had by this time recovered much but not all of its normal intensity.

It would seem evident, then, that, however suited to animals this method may be, the relatively enormous dose necessary for even an imperfect result makes it quite impossible for human surgery.

[This contribution is of peculiar value, since the experiment was performed by the writer on himself, a fact of which he modestly makes no mention in the text. It is evident that the information gained from this first-hand method of experimentation has a far greater validity than that through animal experimentation, although manifestly not widely applicable. — ED.]

## THE SURGICAL TREATMENT OF GONORRHEAL EPIDIDYMITIS.*

BY G. G. SMITH, M.D., BOSTON,
*Assistant Surgeon, Genito-Urinary Out-Patient Department, Massachusetts General Hospital.*

EXTENDING vertically along the posterior and superior borders of the testicle lies the epididymis. This organ arises at the upper pole of the testis, where some fifteen or twenty minute tubules, the vasa efferentia, gather from the rete testis and convey to the epididymis the testicular secretion. In the epididymis, these vasa efferentia unite to form one slender duct, so fine that twenty feet of it are packed into an epididymis an inch and a half long. This duct, very greatly convoluted, with its loops held together by loose connective tissue and the whole surrounded by a tough fibrous jacket covered laterally with serous

* Read before the Surgical Fortnightly Club.

membrane, constitutes the epididymis. From the lower pole of the epididymis it emerges, much coarser and stronger, as the vas deferens.

When, during the course of a gonorrheal urethritis, the specific cocci invade this portion of the genital tract, they set up a more or less severe inflammation in the connective tissue between the convolutions of the spermatic duct. According to Hagner, an exudate forms in the interstitial spaces, causing a swelling which, confined by the tough fibrous investment of the epididymis, presses upon and occludes the lumen of the seminal canal. Pools of secretion, thick with leucocytes, spermatozoa and cellular débris, form behind the obstruction. In the devitalized tissue, with its circulation hampered by the pressure, the gonococci thrive. The dammed-up secretion becomes purulent; owing to its formation under tension, there is great pain and much absorption of toxins, evidenced by temperature occasionally as high as 104, and by leucocytosis, at times of more than 30,000.

Frequently, enough inflammation extends through the tissues to cause the formation of hydrocele. This usually persists as a clear yellow fluid, by its pressure a hindrance to the testicular circulation and a potent cause of pain. The fluid has occasionally been proved to contain gonococci, and not rarely has floating in it shreds of fibrin, or is tinged with blood. In very severe or persistent cases, in lieu of a hydrocele there has been found a thick friable blanket of exudate covering the epididymis and testicle.

In appearance, the epididymis is enlarged to several times its normal size, deep red or purplish in color, with at times blanched areas due to the extreme tension within the sac. Practically the same appearance has been produced experimentally by the injection of methylene blue through a pipette inserted just through the fibrous coat. Upon palpation, the epididymis feels of stony hardness, especially at the globus minor. The central portion is always least affected.

If the process is mild, it may not advance beyond the stage of primary inflammation; on the other hand, it may go on to the formation of tiny abscesses, and to the production of sterility upon the affected side from cicatricial stenosis of the seminal canal.

Not until recent years has this process been recognized as being peculiar to the epididymis. Formerly the testis was thought to be the main site of the disease. It was with that idea that Pirogoff, in 1852, punctured the testicle for relief of pain, and that Henry Smith, an English surgeon, published in the *Lancet* for 1864 a report of many cases of gonorrheal "orchitis," as he called it, treated by stabbing the testicle with a slender bistoury. This idea came to him as the result of a mistake in diagnosis. Thinking a patient had an abscess of his testis, Smith incised the tumor with a bistoury. Instead of pus, a knob of testicular tubules protruded. Smith reduced the hernia, strapped the wound together, and, much chagrined, sent the patient home. Two days later the man's condition had improved remarkably; Smith, upon considering the unexpected result, concluded that the relief of intratesticular tension was the keynote of successful treatment of the malady. Thereafter, all his cases of gonorrheal inflammation of the testicle were treated by puncture with a bistoury. At this same period, we are told, the same procedure was in vogue at the Hôpital de Midi in Paris.

Whether the treatment was too heroic, or whether, in those days of sepsis, some disaster following the introduction of a new infection made the remedy worse than the disease, is not recorded. The method fell into disuse and was practically forgotten by the great body of surgeons until, in 1903, Baerman, of Professor Neisser's clinic, investigated the subject. He described a series of twenty-eight cases treated by puncture of the epididymis, and advanced the first sound surgical principles in regard to the disease. These are so true to-day, and underlie so completely all operations for relief of epididymitis, that they will be given now.

They are:

1. In a considerable proportion of cases of epididymitis, abscesses develop.
2. Suppuration in the epididymis is regularly followed by hydrocele.
3. Gonococci are occasionally found in the epididymis years after the initial urethritis has ceased.
4. Early puncture is advised to save the canal from occlusion.
5. The accompanying hydrocele should be punctured to improve the circulation.
6. Incision and drainage should be practiced more frequently.

Notwithstanding the truth of these principles, they were not put into general application for several years.

Interest in the question in this country was first aroused by Belfield, of Chicago, who in 1905 wrote an article under the title of "Pus Tubes in the Male." He advised incising the epididymis in its long axis for about an inch and suturing the cut edges of the epididymis to the lips of the skin incision.

In May, 1906, Bazet, of San Francisco, published his operation, which he had been practicing for almost nine years, and claimed good results in some sixty-five cases. His custom was to cut down upon the epididymis along the ligamentum scrotale, thereby avoiding entering the tunica vaginalis, and after incising the epididymis, as Belfield advised, to pack the wound with ichthyol gauze. That this operation still has some adherents is shown by a report published in April, 1909, by Louis Gross, also of San Francisco, who had applied it to ten cases.

The man who really brought the operation into prominence in America, however, was Francis W. Hagner, of Washington, D. C. His first communication appeared in the *Medical Record* for Oct. 13, 1906, five months after Bazet's article had appeared, but quite independently. Hagner went much more thoroughly into the pathology of the disease, and reported his cases, six in

number, in a thorough, scientific manner. The operation which he developed, which is now used with modifications at the Massachusetts General Hospital, he performs as follows:

The patient is prepared and anesthetized, as local anesthesia does not suffice. An incision from 6 to 10 cm. in length is made vertically on the outer anterior aspect of the scrotum, over the junction of the epididymis with the testicle. The incision is carried through the tunica vaginalis. The hydrocele is evacuated, the testicle turned out and wrapped in warm moist towels. The epididymis is punctured with a tenotome through the fibrous covering, the greatest number of punctures being made where the induration is greatest. The point of the knife is carried through the fibrous coat into the connective tissue, where lessened resistance is felt. If pus is found, the cavity is evacuated, after a probe is inserted, by light massage, and the cavity syringed out with 1-1000 mercuric chloride, followed by salt solution. The tunica is closed with a running suture of catgut, a cigarette wick placed to the sutured tunica and the skin closed up to the wick.

With our ever-decreasing reliance upon antiseptics, the corrosive wash is now omitted. In the operation which I have seen, the wick was of rubber tissue simply, was led into the tunica, and the tunica was not sutured independently.

In his first paper, Hagner based his conclusions upon only 6 cases. Subsequent reports, published by him in 1909, give a total of 33 cases, — not an immense number, it is true, for he operates upon only 10% of all the cases of epididymitis which he sees. In these 33 operations, pus was discovered in 25, suppuration being about four times as frequent in the globus minor as in the globus major. In 5 of these cases gonococci were isolated from the pus. In one case where they could not be obtained from the pus, they were grown from the hydrocele fluid. No contaminating organism was ever found. In 2 cases there was no fluid in the tunica, but the opposed walls were adherent with plastic lymph.

The results which Hagner claims are absolute relief of pain, disappearance of general symptoms and permanency of cure. Only one of his 33 cases required morphia after operation. He had but one recurrence. The temperature and pulse always fell to normal within thirty-six hours, the greatest drop being from 104 to 98.6 within twenty-four hours. Leucocytosis was diminished, the maximum fall being from 33,000 to 8,400 within forty-eight hours. The average number of days during which patients were confined to bed was five, and only one case was confined to bed for more than seven days.

As for the final results as regards function of the testicle, there are no statistics. Hagner, massaging the affected side, obtained motile spermatozoa, but was not positive that they had not come from the unaffected vesical.

With a view to comparing results at the Massachusetts General Hospital with those of the above writers, and with those of unoperated cases of gonorrheal epididymitis, all cases recorded as such at the Massachusetts General Hospital were looked up. There were 2 not operated upon. One had at entrance a temperature of 104, which became normal in two days. In six days he was discharged, and in six weeks, according to the Out-Patient Department record, his epididymis felt normal. The other case ran an irregular temperature for five days after entrance, during which time he was "uncomfortable."

To contrast with these, there are records of 5 operated cases. One had a temperature of 101, the other of 102, both reduced to normal inside of forty-eight hours. No case had any pain after operation. They were discharged in respectively, eight, seven, five, five, three days. The seven-day case had a double epididymitis, from which all tenderness had disappeared within eleven days after operation. The Out-Patient Department record carries us no further. The end results of three are quite unknown, hence we may suppose there was no further trouble. The epididymis of the fifth man, six weeks after operation, showed very little induration.

It is an open question whether the ordinary case of gonorrheal epididymitis, if kept in bed with tight bandaging for three to five days, would not do quite as well as one which had been operated upon. The severer cases, with excruciating pain, marked toxemia and prospects of serious injury to the testicle, as well as the obstinate recurrent cases, seem to be fit candidates for epididymotomy. The conclusions given by Hagner and justified by the experience of eight or ten other operators sum up the situation thoroughly. They are as follows:

1. According to the known pathology, epididymotomy is a rational procedure.
2. If care be exercised, the danger is slight.
3. The infiltration disappears more quickly than with any other method.
4. The danger of permanent injury is lessened.
5. There is absolute relief of pain.
6. Systemic symptoms are promptly relieved.
7. Medical treatment offers relief but no permanent cure.

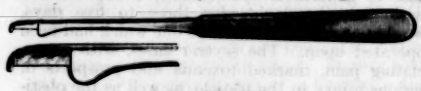
## New Instrument.



### A NEW TONSIL KNIFE.

BY OLIVER P. LOTHROP, M.D., BOSTON.

By the use of a new tonsil dissecting knife of the following design it is believed that great assistance will be afforded to those who do a capsule dissection of the tonsils. The initial incision of the mucous membrane around the tonsil near the inner edge of the pillars and the starting of the

plane of cleavage upon the capsule is the most important and difficult part of the operation of tonsillectomy. It is this part of the operation that the new knife carries out most perfectly with one sweep around the tonsil. With a straight, sharp-pointed scalpel it is often difficult to make an exactly continuous incision of the same depth around the circumference of the tonsil. Uncut fibers thus left prevent the pushing back of the pillars and the exposing of a clean capsule, and one is led to think that the tonsil is adherent. A too deep cut extending into the tonsillar tissue may cause annoying bleeding. A right-angled knife fails because the point may enter the tonsillar tissue or pillar instead of entering just over the capsule. Of such knives, two are required, one for each side. The model presented is equally efficacious for either side and for both pillars and supratonsillar fossa. When a dissector is used to push back the incompletely severed mucous membrane, considerable strain is put on the tonsil, frequently causing the tenaculum to slip off or tear through the tonsillar tissue. This annoyance is avoided with the new knife.

This knife is straight and measures 7½ inches. It resembles a bistoury. There is a single cutting

Codman & Shurtleff.

edge about ½ inch long. The point is blunt and the rounded tip extends at a right angle a trifle beyond the cutting edge of the blade. At the junction of the blade and shank there is a projection which prevents the cutting edge from coming in contact with a tongue depressor and protects the tongue when no tongue depressor is used. The shank is long and is flattened laterally. The hollow handle is likewise flattened. The knife should be kept very sharp. It can be sharpened easily on the cornered edge of a small whetstone.

The technic is as follows: First the tonsil is grasped with a curved tenaculum and drawn inward and a very short incision parallel and internal to the inner edge of the anterior pillar is made with a sharp, pointed scalpel, just through the mucous membrane of the plica down to the capsule. This exposes the outer surface of the capsule for instance about ½ inch. The knife is now passed under the tenaculum and the blunt point is inserted into the incision, between the mucous membrane and capsule. The blunt and rounded point will follow the curved plane of the capsule, and the cutting edge of the knife will incise the mucous membrane as it proceeds downward and under the tonsil. The projection of the rounded point at a right angle to the cutting edge prevents the knife from slipping out when once engaged. After cutting the mucous membrane anteriorly and inferiorly, the knife is reinserted over the tenaculum at the initial point, but turned with the cutting edge up. The blade is now carried up and over the tonsil, through the supratonsillar pillar and down between the tonsil and posterior pillar. As the knife passes over the upper pole of the tonsil, the tenaculum is carried to the corner of the mouth of the same side, thus turning the tonsil forward and outward. This allows a view and access to the posterior pillar. At all times the handle of the knife should be held near the corner of the mouth opposite the tonsil being operated. The left hand should be used in operating upon the left tonsil.

It has been found that the dissection of the capsule is started so perfectly by this continuous incision that the tonsil is partially enucleated and no dissector is required. The snare can be applied at once, this being the easiest and safest way to complete the shelling out of the tonsil with its capsule.

## Clinical Department.

### ANTIPERISTALSIS IN THE INTESTINE. A CLINICAL OBSERVATION.

BY FRED T. MURPHY, M.D., BOSTON.

ANTIPERISTALSIS in the large intestine has been observed experimentally by Cannon [1] and others. A case is reported by Mauclaire [2] in which, after implantation of the ileum into the lower descending colon, section of the colon above the anastomosis was necessary before the content of the gut would pass wholly downward. Stierlin [3] quotes a case of Wilms in which the same antiperistaltic action was observed. Other definite clinical observations supporting the experimental findings have not, so far as I know, been recorded. In order to add clinical evidence to the experimental on this question of antiperistalsis in the large intestine, the following case is reported.

CASE N. W., female, thirteen years of age, colored. Entered Massachusetts General Hospital accident room Sept. 14, 1908, service of Dr. Balch, to whom I am indebted for the privilege of operating. The history was that of appendix which had gone on to abscess formation. Temperature 101, pulse 120, white count of 10,000. Operation was advised and the patient immediately prepared. Three-inch right rectus incision separating the fibers of the muscle. Peritoneum was opened without incident. The exploring finger freed a little muco-purulent fluid and showed a matted, hard omentum packed about the ileocecal valve. The omentum completely walled off the general cavity from the ileocecal region, and in the manipulation the adhesions were not broken down. The cecum was with difficulty exposed and a retrocecal appendix removed.

In exposing the cecum the outer wall was torn. On account of the induration of the tissue it was impossible to close this rent, and a drainage tube was tied in. The extent and character of the adhesions suggested a general tuberculous process. The patient made an uneventful immediate recovery.

Feces were passed through the drainage tube. The acute symptoms subsided, but after a few days there began to be an evening temperature of 101–102. The general condition was not good. On Sept. 30 the drained

[1] Am. Jour. Physiol., 1902, vi, 265.
[2] Cong. de Chir., Paris, 1903, p. 86.
[3] Zeit. für Klin. Med., 1910, lxx, 376.

incision was packed and closed with running suture, then sealed over with collodion dressing. A second incision was made in the median line and parallel to the old. The peritoneal cavity was opened without incident. The lower ileum was exposed and freed from adhesions. The general abdominal cavity was found to be a mat of adhesions, the intestine being studded with small nodules. At the time of the operation the intestine was inspected by Dr. William F. Whitney, who gave a diagnosis of tuberculous peritonitis, but in some way the specimen taken for microscopical examination was misplaced. After freeing the lower ileum for about six inches it was cut across just above the ileocecal valve. The distal loop was turned into the large gut and closed with Lembert suture. The proximal end was implanted end-to-side into the large intestine, well beyond the median line of the transverse colon. Adhesions made orientation difficult, but the implantation was certainly to the left of the median line. This incision was closed tight.

During the first forty-eight hours following the operation the fecal fistula remained clean. During the next twenty-four hours the discharge was as profuse as ever. On Oct. 4 the patient had several normal movements and there was less discharge from the fecal fistula.

For the next month the condition remained practically the same. The lower bowel could be emptied by enemata of small fecal movements, but the fecal discharge from the colostomy wound remained as profuse as before the anastomosis between the ileum and the transverse colon.

On Nov. 9 the patient was removed from the hospital, against advice.

In this case there can be no question of the antiperistaltic action of the large bowel. The descending colon and rectum were patent, as was shown by the normal bowel movements on Oct. 4, but with this normally patent lower bowel the fecal stream entering the large intestine to the left of the middle of the transverse colon was continuously discharging through the cecal opening for a month at least.

## Medical Progress.

### REPORT ON OBSTETRICS.

BY ROBERT L. DE NORMANDIE, M.D., BOSTON.

#### OPHTHALMIA NEONATORUM.

In the past year great advance has been made in attacking ophthalmia neonatorum in Massachusetts. By the Acts of 1910, Chapter 458, the State Board of Health was empowered to distribute free to all registered physicians in the state the necessary preventive. That has been done and a 1% solution of silver nitrate in a dropper has been sent to every registered physician. With it was sent a most specific letter concerning the disease and the necessary steps that should be taken to prevent destruction of the eye should ophthalmia develop. All physicians in the state have now been notified that the disease must be reported at once. All physicians in Boston have further been notified by the Boston Board of Health twice that this disease must be reported. No physician can now with any degree of honesty deny that he has been notified of the law. It plainly showed that the boards of health had every intention of treating the physicians fairly and the physicians can now plead no lack of knowledge or any extenuating circumstances. There is a widespread feeling to-day among physicians that this law refers to gonorrheal ophthalmia only. By a wise proviso, there is no reference to that disease. By reporting it, there is no shame brought to the child's family. A conviction has been obtained in the Suffolk Superior Court for failure to report a non-gonorrheal case even when the eyesight was saved. The law only says if the eyes "become inflamed, swollen or red, and show an unnatural discharge within two weeks after birth." Since the various warnings have been sent out, the number of cases reported has much increased, but even with this improvement seven infants were brought to the Massachusetts Eye and Ear Infirmary during 1910 totally blind from ophthalmia neonatorum. It is estimated that rearing each infant to the age where the Massachusetts Commission for the Blind can help it to useful work means an outlay of about three thousand dollars. In other words, these seven infants are going to cost the state roughly twenty thousand dollars, provided they live, before they become of any value whatsoever to the state. Throughout the state there must necessarily be, because of all the literature that has been freely sent about it, a change in the attitude the laity will take about ophthalmia neonatorum. It has been well shown that practically every case of ophthalmia neonatorum may be cured if taken in time and adequate treatment be given. The laity will soon realize that in any case of blindness the physician in charge in a very great majority of cases is to blame because adequate means were not taken early enough. The State Board of Health through its district inspectors are following up all cases of ophthalmia to see that sufficient treatment is carried out, and further than that, the State Board writes a strong letter to all physicians who may neglect to report the cases of ophthalmia at once.

The Massachusetts Medical Society recognized two years ago the seriousness of this destructive disease and appointed a committee to give advice about it. This committee sent to each member of the society a statement concerning the treatment which has given the best results.

The Boston Board of Health has charged four physicians with neglecting to report their cases. One physician in East Boston was fined, but the judge, the next morning, revoked the fine. Two other cases were tried and found guilty. The fourth case, a Roxbury physician, was tried January, 1911, but was not convicted. Trials, convictions or non-convictions will go far to prevent greatly the number of blind children in this Commonwealth. The law in regard to this disease is clear and has been tested in court and found sufficient. With the notices that the State Board of Health has sent out, and the advice that The Massachusetts Medical Society has given, and in Boston that which the local Board of

Health has given, a splendid impetus has been given to prevent entirely this wanton destruction of eyesight. As a result of the various local investigating committees on the prevention of blindness, last December, there was formed in New York a national Association for the Prevention of Blindness and the Conservation of Vision. Much educational work has been accomplished, and still more is to be done. The necessary laws and warnings have been given. It remains now for each city and town board of health to take the necessary action to wipe away this unnecessary blindness. The conscientious physician is not the offender. From various investigations it apparently is not the illegal midwife, but is the poorly trained unscrupulous physician who is practicing medicine as a business and not as a profession.

### PHARMACOLOGY OF ERGOT.

Wood and Hoffer[1] have carried out a series of experiments in order that the preparations of ergot on the market may have the same strength and the same pharmacological action. Their conclusions as regards the quality of ergot that is at the disposal at the present time of physicians are as follows:

(1) Preparations of ergot obtained from retail pharmacists are almost universally below the standard.

(2) No preparation of ergot which does not contain considerable amounts of alcohol or some similar inorganic solvent can thoroughly represent the drug.

(3) Starting with an active specimen of the crude drug, the fluid extract, freshly made according to the process of the eighth revision of the United States Pharmacopeia, will furnish a potent preparation.

(4) Both the crude drug and the fluid extract deteriorate comparatively rapidly.

(5) They recommend that all preparations of ergot should bear on the label the date of their manufacture, or at least the date beyond which the strength of the specimen cannot be trusted, as do the antitoxic serums, and should be preserved in small bottles hermetically closed.

### THE SURGICAL TREATMENT OF PUERPERAL SEPTIC INFECTION.

Vineberg[2] regards the indications for surgical interference difficult to formulate for the reasons that there are no reliable guides either clinically or pathologically as to the course and prognosis of a given case. Puerperal septic infections show a marked variety of lesions with varying degrees of intensity. There is only a very small percentage of cases where major surgical operations come into the question at all. He follows Bumm's classification of a general streptomycosis (pure septicemia); second, the localised streptomycosis. In the first class the patient generally dies within a few days of continued high fever with rapid destruction of the red blood cells. Any surgical procedure in this class is probably useless with our present means of diagnosis. In the second class, there is a marked tendency to localize the infection in an affection of the lymph channels of the uterus or of an endophlebitis rapidly extending over the uterine sinuses and the vena cava. With a septic lymphangitis or septic thrombophlebitis the bacteria may or may not be in the blood. Presence or absence of streptococci in the blood Vineberg regards as no reliable criterion as to the malignancy or non-malignancy of the infection. He refers to sixty fatal cases of puerperal sepsis where a negative blood culture was found thirty-eight times, while a positive was only found in twenty-two. Freund and Bumm first ligated only the spermatic veins, and it was Trendelenburg who showed that the hypogastric or internal iliac veins were also oftentimes involved. In the diagnosis of a septic thrombophlebitis Trendelenburg lays stress upon repeated chills, and he advises operating on the occurrence of a second chill. This Vineberg disagrees with. Vineberg feels that the great elevation and depression of the temperature curve within the twenty-four hours, usually associated with the marked rise and fall of the pulse, is especially suggestive. The pulse and quality is good, subjective symptoms are few. The patient's appearance is usually good; the pelvic and abdominal examination often negative. Some observers say that they can palpate the thickened and thrombosed veins. The diagnosis is made by the negative results of our local examination and by the process of exclusion rather than by any positive finding.

Vineberg describes his technic with two illustrations. Other forms of puerperal sepsis, — putrid endometritis, severe traumatism of the uterus with probable infection, septic salpingo-oöphoritis and pelvic exudates, he briefly reviews.

### CÆSAREAN SECTION IN THE PRESENCE OF SEPSIS.

Maxwell[3] reports a case of a patient upon whom he did a Cæsarean section after labor had progressed forty hours and the membranes ruptured. Forceps delivery had been attempted and failed. Patient's pulse was 110, normal temperature. Fetal heart 120–130, normal and regular. The only difference in technic that Maxwell carried out was that before doing the section the uterine cavity was washed out with sterile salt solution, the temperature of which was 105° F. Maxwell felt that this temperature would be reduced to 100 by the time it got into the uterus, and probably would not induce premature fetal respiration. He used several quarts of the saline solution and the fluid escaped freely. Recovery of the patient was uncomplicated and the baby lived.

The mere washing out of the uterine cavity with salt solution probably did not prevent this patient developing sepsis. Good fortune rather than good obstetrics is here evidenced.

### THE INFLUENCE OF PREGNANCY AND LABOR UPON DISEASES OF THE EYE.

Germann has raised the question whether the induction of abortion and premature labor is justified when the vision is endangered by the pregnancy. He wrote especially of albuminuric retinitis, detachment of the retina, choked disk and the various forms of inflammation of the optic nerve. He also reported four cases of serious purulent keratitis which began during pregnancy or lactation. His conclusions are that the preservation of the mother's sight is of much more importance than the life of the child and that physicians should lay more weight upon the health of the eyes of the mother and that they should not delay in inducing abortions when the vision of the mother is endangered.

Fejer[4] in his book writes that obstetricians have paid but little attention to the connection between pregnancy and the diseases of the eye. Chronic nephritis and the retinitis caused by it form unqualified indications for the termination of pregnancy. In choked disk likewise the termination of pregnancy is useful as well as in purulent keratitis. Kneis, Schmidt, Rimpler, Groebouw, Axenfeld, Silex, Cohn, Berger and Runge, Fejer says, have all studied the connection of eye diseases with general and uterine diseases and have without exception declared that in all cases in which pregnancy is complicated by eye diseases, particularly of the retina or optic nerve, the nutritive condition of the mother, the condition of vision, the objective changes in fundus, the social conditions of the parents and the desires of the mother must all be taken into account in the question of inducing abortion. Fejer reports a case of a woman thirty-five years old who had myopia and was two months' pregnant and the mother of three children, who came to him with her husband to ask what probable influence pregnancy would exert upon her eyesight, for she had noticed that after all of her three previous confinements her myopia had increased very markedly. Her eyes showed a marked myopia. In the fundus there was a circular conus half the size of the papilla and there were chorio-retinal changes in both eyes. Fejer, on careful consideration of the facts, advised abortion and this was done, with the result that the myopia did not progress up to the present time, which has been three years. Fejer concludes that the declaration of the patient that the myopia advances greatly after confinement should not be passed over lightly and that all the points above enumerated should be taken into consideration, consultations called and abortion induced oftener than is the present case.

### CÆSAREAN SECTION BY THE SMALL MEDIAN INCISION ABOVE THE UMBILICUS.

Davis[5] reports the points of interest in 256 cases of Cæsarean section at the New York Lying-In Hospital. The maternal mortality was 14% and the child mortality was 12.74%, with stillborn cases of 7.34%. In ten of the cases Davis operated upon himself, the operation was done twice, in one case three times and in one case five times. Rupture of the uterus was found twice in patients upon whom Cæsarean section had previously been done, and both of these cases had gone on in labor forty-eight hours without reporting to the hospital. Davis says that the still relatively high maternal mortality is largely chargeable to the broadened field where the operation is now used and not to the operation itself. Davis feels that in eclampsia Cæsarean section is the safest and quickest way to deliver the patient. In the past nine months he has done eighteen Cæsarean sections on eclamptic cases with the result that fifteen mothers and thirteen children were discharged from the hospital well. Davis favors the enlarged broadened indication for this operation and chooses, when possible, the very beginning of labor, thereby making no mistake in the development of the child. The only real difference in technic that he recommends is the opening of the abdomen by the high median incision 8–10 cm. from above down to the umbilicus. A small gauze dressing is held in place by tight adhesive straps across the wound only and supported by a binder which is tight only across the wound. By this means the uterus is allowed free play in the lower abdomen. The head of the bed is raised to favor drainage. The patient sits up in a chair the eighth day and is discharged on the twelfth day. Davis does not render the patient sterile because of the many successful repeated sections that have been performed there. There is no need for haste in doing the operation and he says it should be done with deliberation, and when done otherwise, great danger arises. The objects gained by the high incision are that it does not allow easy exposure or escape of the abdominal contents. The wound is away from the site of greatest strain. It is small and the liability to adhesions between the abdominal wound and the uterine wound is greatly diminished. Davis says he has never seen a hernia following it.

### ORIGIN AND PREVENTION OF PUERPERAL FEVER.

Doederlein[6] says of the many factors in puerperal infection, two stand out with clearness, (1) infection from within the female generative organs themselves and (2) inoculation by pathologic organisms from without during labor or the puerperium. The flora of the vagina, he says, gives extensive protection against virulent infection at least during pregnancy and during normal labor. Only one definite micro-organism, bacillus vaginæ, has its natural habitat there. The bacillus plays an important rôle in preventing the growth of other micro-organisms by the production of lactic acid. Doederlein carried out a series of experiments to determine whether disinfection of the vagina gave better or worse results than non-disinfection, the rest of the technic in the delivery being the same. The only difference was, in the first series, the vagina was scrubbed out as gently as possible with a 1-1000 sublimate solution, while in the second

series the vagina was left absolutely alone. He found that the patients where so-called disinfection was practiced were twice as badly off as regards fever as those who had been disinfected. Doederlein says that when the vaginal flora are disturbed by disinfective measures the chances of parturition remaining entirely physiological are decreased. To prevent disinfection by the second cause he demands that examination be made only by gloved hands. In order to reduce the cost of gloves, he has had made a two finger glove so that now they can come within everybody's means.

### B. COLI INFECTION OF THE URINARY TRACT COMPLICATING PREGNANCY.

Burnett,[7] in a most thorough and interesting article, writes on the infection of the urinary tract by micro-organisms during pregnancy. He finds that in French and German literature there has been more written on this subject than in Great Britain. He does not speak of any work on pyelitis that has been done in this country. He reports four characteristic cases of pyelitis with the chemical findings of the urine, also the bacteriological findings. He finds no system of classification entirely satisfactory, but divides them into acute cases; second, chronic cases, and third, slight or evanescent cases. The disease may show itself as early as the fourth month and probably appears the most frequently at the fifth or six month. Burnett thinks it is more frequent in primigravidæ, though it may complicate any subsequent pregnancy. The acute cases divide themselves into those with bladder symptoms and those showing a renal disturbance with few if any bladder symptoms. This second group constitutes the great majority of cases. In this type the patient is seized with sudden rigor and temperature accompanied by diffuse abdominal pain. Nausea and vomiting are not infrequent. The urine is scanty and high colored. In some cases there is frequency of micturition. Physical examination shows rigidity of the abdominal muscles, especially on the right side. The patient complains frequently of pain about the appendix area as the site of the greatest suffering. Palpation shows tenderness most frequently over McBurney's point. Burnett feels that the most characteristic feature of the physical examination of this condition is the extreme hyperesthesia over a wide area in the right kidney region. Burnett feels so strongly that this is invariably present that he has come to feel that when a patient has a pain over McBurney's point accompanied by right-sided hyperesthesia in the costo-vertebral angle that the case is more likely to be an infection of the urinary system than of the appendix. Examination by vagina may show tenderness over the whole of the posterior bladder wall. In a large percentage of cases there is a tender spot where the right ureter enters the bladder, and the ureter here may be thickened and dilated so as to be readily palpable. Temperature may be up to 104° with a marked remission in the morning. Fever is usually preceded by a chill. After the first few days of onset, the intermittent aspect of the temperature chart disappears. The temperature may be persistently high, indicating either involvement of the renal tissue or that the bacillus has attacked some other organ. The pulse-rate remains comparatively low, from 100–110, until some complication arises. Pain is invariably present, the location of which is doubtful, referred either to the upper or lower part of the urinary system. The wide area of hyperesthesia is most important. In the majority of cases the urine has no characteristic smell, when the infecting organism is purely B. coli. There is no ammoniacal odor for this organism has no power to split urea. The urine may be passed in moderate amount with or without frequency or pain. It is turbid, which is due partly to the presence of mucus, also to the presence of flakes of lymph and shreds of epithelium and pus cells. The reaction is invariably acid when the B. coli is present in pure culture. If the infection is mixed, the urinary reaction may be neutral or even alkaline. The specific gravity shows no marked abnormality. Sugar is rarely present. Albumen is usually present in small quantities and there may be a small amount of blood. By the microscope, pus cells are present in more or less abundance. B. coli are recognised usually in pure culture. Burnett feels that the only way of definitely distinguishing the source of the pus is a careful study of the clinical symptoms plus a cystoscopic examination with ureteral catheterization. The acute cases untreated run a course of several weeks with deepening toxemia and repeated rigors. In the chronic type the onset is more insidious and shows malaise, muscular pains and irregular temperature. Bladder symptoms may be slight or absent entirely. Pain and tenderness in the kidney region is always present, though not nearly so marked as in the acute cases. The slight cases are naturally overlooked, Burnett feels, but given a pregnant woman complaining of intermittent attacks of "lumbago" with griping pains especially over the right side, the urine should be carefully examined for evidence of B. coli infection.

In the bacteriology of these cases the colon bacillus is the most frequent, but is not the most serious, as both the streptococcal and staphylococcal infections are much more dangerous. The question of the severity of mixed infections is still an open one. The following points in the clinical picture Burnett regards as important: (1) Rigor with sudden elevation of temperature occurring in a pregnant woman in good health. (2) Sudden onset of acute abdominal pain, especially on the right side. (3) Attacks of "lumbago" during pregnancy. (4) Well-defined tenderness in the appendix area and associated with a wide area of hyperesthesia over the right renal region. (5) Acute abdominal distention, sometimes so marked as to cause respiratory embarrassment. (6) A pregnancy cystitis that persists in spite of customary treatment. (7) Pyuria in pregnancy.

In the differential diagnosis, appendicitis, acute intestinal obstruction, renal or ureter stone, malaria and pneumonia with pleurisy, all must be carefully considered and ruled out by a careful examination of the urine in all cases. Burnett feels that the etiology of the disease is very complex and obscure. There are two ideas as to how the bacillus gains access to the urine — either an ascending infection or a descending, hematogenous infection. There is much to be said in support of both views. The marked unilateral frequency of the disease especially affecting the right side is very prominent. Several explanations are given, though none can be proved. In the treatment, rest in bed, attention to the bowels, bland diet and forcing fluids will readily procure relief in the mildest cases. For medicinal treatment, Burnett gives large doses of citrate of potassium or sodium, 30–40 gr., every three hours. Burnett says he is unable to explain the rationale of their action, for theoretically one would expect that making the urine alkaline the bacteria would thrive better in an alkaline media than in an acid one. Urotropin he has been disappointed in its action when an infection is due to a pure culture of the B. coli. With a mixed infection it is a distinct advantage to use it. Serum treatment has not as yet proved satisfactory. In the operative treatment, nephrotomy or interruption of pregnancy by emptying the uterus may occasionally, he says, be necessary.

He recommends interruption of gestation in very severe cases where the ordinary palliative treatment has been unavailing rather than submit the patient to a nephrotomy.

### CÆSAREAN SECTION FOR IMPASSABLE CONTRACTION RING.

Dickinson[8] says that Cæsarean section is warranted in the presence of an impassable contraction ring when the following conditions are present:

(1) Child living and not definitely enfeebled or endangered by length of labor, long drainage of waters or unskilled attempts at extraction.

(2) Ring refuses to relax under morphia or to yield to complete etherization, coupled with patient manually dilated by a skilled obstetrician.

(3) Mother in fair condition for a laparotomy and not infected.

(4) Request by patient and husband that a somewhat increased risk to the mother be assumed for the sake of obtaining a living baby in lieu of embryotomy.

And that these conditions are perfected if

(5) At a previous labor in expert hands this same condition of the contraction ring has caused loss of a child not unduly large.

He then reports a case of his own where he did a Cæsarean section with the above conditions fulfilled. The patient had been in poor labor for at least forty-eight hours when the section was decided upon. Both patients made a good convalescence. He gives details also of three other cases which were treated the same way. In two of these cases the mother died, but all the babies were saved. He reviews the study of contraction rings, going over the etiology, the diagnosis, the mortality to the mother and to the children and the treatment which may be instituted. The treatment of a contraction ring he divides as follows:

Relaxation by rest induced by morphia, by anesthesia to a surgical degree, dilatation by hand, by bags and by traction, embryotomy, Cæsarean section with the removal and without the removal of the uterus. He says Cæsarean section has a narrow but well-defined place, as is shown by his first remarks. Dickinson ends his paper by saying that Cæsarean section is safer than embryotomy in the worst degrees of ring contracture and tetany.

There is no question but that occasionally, or, better, very rarely, we are driven to do a Cæsarean in spite of our realising that the operation is contra-indicated. One of Dickinson's main points in the indications for doing a Cæsarean for an impassable contraction ring is the fact that the patient is not infected. One cannot always definitely state, but there is no question but we can take it as a law in obstetrics that the chances are very much in favor of infection when a woman has been in labor forty-eight hours or longer and has had any operative interference no matter under how good technic. There is a certain percentage of cases no doubt where the classical Cæsarean section will be done and both mother and child saved. Such a case is the first one reported by Dickinson. In Dickinson's summary he says that a third of the mothers and half the children died in the reported cases of impassable contraction ring. He has reported four cases where a Cæsarean was done. In these cases 50% of the mothers died, while all the children were saved. From an obstetrical point of view the four cases which he reports were badly managed. It surely cannot be regarded as the best obstetrical teaching to allow a woman to be in labor twenty hours with membranes ruptured and complete dilatation for six hours with good labor pains going on all of this time, or is it good obstetrics to allow a case to go on in labor fifty-two hours in the first stage and then after hard operative attempts at delivery to do a Cæsarean. Or in the fourth case, is it good obstetrics to allow a patient to continue four hours in the second stage without progress and then to have forceps applied and traction made for one-half hour with negative results and then to do a Cæsarean section. In his article he says it is unfortunate that the diagnosis of contraction ring cannot be made until the labor is well established for the reason that the contraction ring has no existence save during the act of labor. Therefore, as an indication for Cæsarean section, it cannot be classed with the indications for primary sections. In Dickinson's summary we find him recommending Cæsarean section on a dead fetus with an undilatable contraction ring, provided, of course, that the case is not infected. The criticism of this article is that it is the case, apparently, nowa-

days that one turns to Cæsarean section as a justifiable operation for any obstetrical complication. In the matter of diagnosis these four cases that Dickinson reports all should have been suspected. The long slow labor of poor character, without force and without advance, should lead one to suspect a contraction ring, and if one is suspected, the time to operate is at the beginning of that contraction ring and not after it has gone on and become an impassable ring. Dickinson is favoring a major operation where it has been conclusively shown that the mortality rate is very high. By his own article he has shown that he has increased the mortality rate from 33% to 50% in the mothers, though to be sure he has reduced the mortality rate in children to nil.

### DURATION OF PREGNANCY WITH A NEW RULE FOR ITS ESTIMATION.

McDonald [9] reviews the much-debated question of duration of pregnancy and shows that there seems to be conclusive proof that pregnancy may persist for longer than two hundred and eighty days and that when it is prolonged the resulting chill is commonly of large size. In order to determine the date of labor, McDonald has evolved a rule which is dependent upon the height of the fundus above the symphysis. The rule is as follows:

The duration of pregnancy in lunar months is equal to the height of the uterus in centimeters divided by 3.5. In order to take this measurement, the patient is lying flat upon the bed, one end of the tape is placed at the upper border of the symphysis, while the other is held by the palm of the hand. The fingers of the upper hand are held at right angles to the fundus and the tape follows the contour of the uterus except at the last dip. Multiparæ with lax abdominal walls should be supported at the sides when the measurement is taken. McDonald says that this method is very exact after the sixth month, but depends upon the estimation of the size of the fetus. He says that when the uterus arrives at the height of 35 cm. or full term, the fetus is of a weight of 3,300 gm., the average size. He further argues that an average size baby usually comes at the average period of pregnancy, therefore the rule. He further states that for every centimeter of height above 35 cm., approximately 200 gm. should be added to the weight of the fetus. Sinking of the fetus in the last two weeks of pregnancy causes but little error, as the head, he says, when the patient is recumbent, rides upward.

## Reports of Societies.

## MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

THIRTY-SIXTH ANNUAL MEETING, HELD AT DETROIT, MICH., SEPT. 13, 14 AND 15, 1910.

(Concluded from No. 4, p. 135.)

### PULMONARY TUBERCULOSIS AND SYPHILIS, WITH BRIEF REPORTS OF THREE CASES.

DR. ROBERT H. BABCOCK, of Chicago, cited the views of different writers as to the mutual influence on each other of the association of these two infections and showed that the effect of the second infection depended largely on the stage of the primary disease. He then narrated the salient points in three instances coming under his observation in the past year, in all of which pulmonary tuberculosis was developed in the late stage of syphilis with apparently a retarding effect on the tuberculosis.

His conclusions were as follows: (1) The effect of the association of pulmonary tuberculosis and syphilis seemed to depend largely upon the stage of the primary disease during which the second infection was acquired. (2) The acquisition of syphilis during the incipient or early period of tuberculosis appeared to be of a negative influence or even in some instances to exert a retarding or curative effect on the tuberculosis. (3) Syphilis acquired by a consumptive in an advanced stage was likely to aid the downward progress of the tuberculosis. (4) Tuberculosis when developed during the primary or secondary stage of syphilis offered a bad prognosis and was apt to run a rapid course. (5) When pulmonary tuberculosis developed during the third or late stage of syphilis, it was apt to pursue a slow course, probably because of the tendency of the lues to sclerosis during this stage. (6) The association of these two diseases did not preclude the mercurial treatment of the syphilis by intramuscular injections and inunctions, but iodine if administered at all must be used cautiously because of its tendency to hasten softening of the tuberculous foci. (7) During the antisyphilitic medication there should be no relaxation in the hygienic measures recognised as necessary in the management of the tuberculosis.

### PRELIMINARY REPORT OF CASES TREATED BY DR. CARL SPENGLER'S TUBERCULOSIS IMMUNE BLOOD.

DR. W. F. WOOLSTON, of Chicago, stated in his paper Dr. Spengler points out that in previously immunized patients, after an injection of an antigen, the following relative change in position of the stored-up immune substances took place. In about half an hour the quantity of serum immune substances increased, with a decrease in the immune substances of the red blood cells; and in a few days the deficiency in red blood cells had again been balanced or overbalanced and the serum left deficient of these bodies. Dr. Spengler was of the opinion that the leucocytes played a part in the absorption of these bodies. It would be seen that he regarded the erythrocytes as the main source of the production of immune bodies. In healthy animals, after tuberculous poison had been injected, the immune bodies were demonstrable in the red blood cells. They appeared to be adherent to the hemoglobin and could be separated chemically or mechanically.

He had not as yet, in a preliminary paper, with the limited time and number of patients, been able to always say beforehand just which cases would improve. However, the acute miliary had shown the

most striking results, as health had been regained in a comparatively short time. Some of the chronic cases had shown no improvement and two of them seemed to have old lesions stimulated to activity. Some of the untoward effects had been a diarrhea, which had been easily controlled by some mild intestinal antiseptic. In a case of one nine-year-old patient a rash occurred after the first injection which disappeared in twenty-four to thirty-six hours. Among the earliest signs of improvement was the disappearance of lassitude, an improvement in the appetite, a decrease in the amount of sputum and number of bacilli, a gain in weight, an improvement in sleep, and a lowering of temperature and pulse. The toxic pulse, however, took more time to reduce, and sometimes heart stimulants were indicated to aid in the myocardial power. The conclusions of writers who had used this tuberculosis immune blood serum were favorable as to its efficiency

### PROSTATIC HYPERTROPHY.

Dr. John E. Cannady, of Charleston, W. Va., in his paper stated prostatic hypertrophy was the greatest curse of age in man. The chief indications for operative relief of obstruction were difficulty in urination and residual urine. He spoke of the value of bladder irrigation and the administration of urotropin and sodium benzoate. This combination was well borne by the stomach. Matters of diet and water drinking were of paramount importance. The choice of operation, whether suprapubic or perineal, depended largely on the individuality of the operator. The value of suprapubic cystotomy was pointed out. He spoke of Hunter McQuire's method and emphasized the necessity for rapid work. The popularity of the different methods was largely a matter of geography, like chloroform and ether. He spoke of the results of Freyer and Young, and pointed out the advantages of a non-toxic local anesthetic, such as novocain, in doing a cystotomy. Only a brief general anesthesia was necessary for the completion of the two-stage operation. He spoke of the management of the patient before, between and after the various steps of the operation. They should always bear in mind the conservation of the patient's strength. The two-stage operation cut the danger in half. Normal saline irrigation was of great value. The end results were almost ideal in the average case, there being both anatomical and physiological restoration of urethra and bladder. He reported illustrative cases showing the management of the normal case.

### THE INTERPRETATION OF JAUNDICE.

Dr. Charles N. Smith, of Toledo, Ohio, gave an interpretation of jaundice as observed in gallstone disease and its associated conditions — the interpretation of a symptom which was both infrequent and inconstant, and, at best, indicative only of complications, or terminal events.

### DISCUSSION.

Dr. J. H. Carstens, of Detroit, Mich., stated the common everyday catarrhal jaundice was of great importance. It was caused by gastro-duodenal catarrh, so-called. A patient would have jaundice and in the course of five or six weeks it would disappear, and whether treatment had any effect or not he had grave doubts. He had had this form of jaundice himself. He took everything his physicians told him to take,— sweet oil, calomel and many other things,— but the jaundice continued. He then restricted his diet to nitrogenous food, and did not take any kind of carbohydrates, oils, fats, etc., but some good lean beef, some eggs and water, and in a short time the jaundice disappeared.

Dr. R. N. Murray, of Flint, Mich., stated after suffering from jaundice for a considerable period of time and having tried various remedies, at the request of some Flint physician he took hydrochloric ammonia in ten to fifteen grains every two hours, and in four days the jaundice cleared up.

### A NEW PRINCIPLE IN THE TREATMENT OF GRAVES' DISEASE.

Dr. George W. Crile, of Cleveland, Ohio, stated the benefits which followed the ligation of the superior thyroid artery were due for the most part to the break of the nerve supply which was inevitable in the course of the ligation. In Graves' disease the thyroid showed a work hyperplasia, and the brain cells showed a work exhaustion. In Graves' disease the brain sent a more or less constant flow of stimuli into the thyroid gland. The thyroid responded by an increase of its secretion. This increased secretion of the thyroid caused an increased activity of the brain cells. In this manner the brain and the thyroid reciprocally goaded each other, and this deadlock, if not broken, continued until one or the other was worn out. This he believed was the explanation of the curious ending one occasionally observed, namely, the sequence of myxedema and Graves'. Breaking of the nerve connection between the brain and the thyroid gland rendered Graves' disease curable. No case of Graves' disease was cured by operation alone, and no case was cured until the thyroid gland and the brain were both restored to the normal. This was best secured by operating in such a manner that there was no excitation of the nervous system, nor of the thyroid glands; hence no volatile outbursts during or after the operation, and no operative danger; then placing the patient in a rest cure for a month or more, depending upon the severity of the disease. If, on the other hand, the patient after the operation was at once immersed in the environment in which the disease originated, there would be many disappointments. The plan of treatment by a combination of a benign operation, followed by a prolonged rest cure, would restore the patient, in so far as tissues were not already irreparably destroyed, to the bloom of health.

Dr. G. V. I. Brown, of Milwaukee, Wis., read a paper in which he described the surgical operative steps in closure of cleft palate.

### SURGERY OF THE GREAT SCIATIC NERVE.

Dr. B. M. Ricketts, of Cincinnati, Ohio, read a paper on this subject in which he reported two cases of complete severance with subsequent anastomosis. He drew the following conclusions: (1) Compression for sciatic neuralgia hardly justified the effort. (2) Acupuncture with the injection of electricity or medicaments through an open incision was to be recommended. (3) Acupuncture without open incision was most difficult and uncertain to accomplish. (4) The use of a metal wire and tube for direct multiple injections should be encouraged. (5) Stretching the nerve for neuralgia had been more or less beneficial, and second in choice before more radical measures were employed. (6) Neurotomy without suture was to be condemned, but it should be employed before sacrificing any of the nerve tissue. (7) Neurectomy was the last of surgical measures to be employed for neuralgia. (8) Neurorrhaphy (primary or secondary) should be done in cases where the nerve had been partially or completely severed by any cause. (9) The great sciatic nerve might be completely divided and remain

so indefinitely without great loss of sensation. (10) Both sensation and motion might be improved or completely restored by coapting the severed ends with sutures. (11) Small needle and silk were attended with less trauma than those of larger size. (12) Anesthesia might be local or general.

### OFFICE TREATMENT OF ANTRAL DISEASE.

DR. WILLIAM W. PENNELL, of Mt. Vernon, Ohio, stated many simpler forms of empyema were amenable to office treatment. The requisite amount of drainage could be made under cocaine anesthesia. There were cases where tooth extraction and curettement and closure of the alveolar fistula had to be practiced, but these were made simpler by efficient drainage, astringent washes and cleanliness. Even the graver forms were made more amenable to radical operation where drainage and washings had been practiced as preparatory treatment. After drainage had been established, washes of sterile normal salt solution were only medicaments used in simple empyema; while in those having dental complications, extraction of teeth, and those having thickened antral membrane from prolonged inflammation, curettement and the use of astringents were added to the simple washes.

### SURGERY OF MUSCULOSPIRAL PARALYSIS.

DR. A. H. BARKLEY, of Lexington, Ky., read a paper on this subject in which he drew the following conclusions: (1) Many cases had been operated on, but comparatively few reported. (2) In cases of trauma, associated injury of the musculospiral nerve might be and frequently was overlooked. (3) The anatomical position of this nerve rendered it peculiarly liable to trauma. (4) Injuries, such as fractures, falls and blows, were the most frequent cause in the order named. (5) It occurred with equal frequency in both arms, the middle and lower third being the most often affected. (6) The musculospiral was injured more often than any other nerve and not infrequently served as ground for legal action. (7) More frequent in males and might occur at any age, more especially between ten and thirty years. (8) In cases where complete loss of sensation and motor function followed severe injury, the probabilities were that the nerve had been injured and operative interference was indicated. Cases following slight trauma often recovered without operation; however, if no improvement was noticed after two or three months, operation was justified. (9) Secondary cases sometimes presented technical difficulties not present in primary cases. (10) No one symptom was pathognomonic and the pathological condition varied so widely that it was impossible to state before operation with much certainty the exact condition present in a given case. (11) Prognosis was good in clean cases. Especially was this true where operation had been restored too early. One of the most important determining factors was the length of time the injury to the nerve had existed. (12) Operative treatment depended on the individual case; the earlier the operation, the better the result. Small round needles and fine silk had given best results in the hands of the writer. (13) All patients with injuries to the arm, especially fractures, should be impressed with the possibility of musculospiral development.

### THE ACUTE ABDOMINAL MANIFESTATIONS OF SYPHILIS.

DR. LOUIS A. LEVISON, of Toledo, Ohio, in a paper on this subject, summarized as follows: (1) Syphilis showing acute abdominal manifestations was not uncommon, but was not generally recognized. (2) The liver was the organ most often affected. (3) Abdominal manifestations occurred more often in the tertiary stage. (4) Syphilis of the stomach could simulate most of the ordinary gastric diseases. (5) The symptoms of acute abdominal manifestations of syphilis were in no way diagnostic and included pain, tenderness, fever, jaundice, chills and sweats. (6) The gastric crises of tabes might be considered syphilitic in their nature.

### THE WASSERMANN SERO-REACTION TEST.

DR. W. T. MEFFORD, of Chicago, spoke on the value of this test to the physician. As to what class of patients he would recommend for a Wassermann test, he would say that all persons giving a history of syphilis, either inherited or acquired, and all persons with clinical symptoms simulating syphilis, and in late manifestations of syphilis. He would use it as he would a urinary or sputum examination, or blood count, placing the Wassermann test side by side with these as an assistance in making up the clinical findings. In all cases where he got a positive Wassermann or an active syphilis either alone or associated with other diseases, he would put the patient upon mercurial treatment. Of all conditions in which syphilis was associated, where he got the best results in treatment had been in syphilis associated with the heart and arterial system. Next, the liver. He had not got the improvement in tuberculosis associated with syphilis that he expected or had hoped for by specific treatment, or the treatment of syphilis.

### PYLORIC STENOSIS IN THE INFANT.

DR. W. D. HAINES, of Cincinnati, Ohio, reported a case on which he had operated for the relief of this condition. The child was removed to a hospital and a posterior no-loop gastro-jejunostomy was performed. Twenty-four hours after the operation the child showed no distress after taking nourishment and had continued free from his old symptoms. Except constipation, all of the symptoms had disappeared, and though still under size the child was thriving and playful five months after operation.

### PLEURAL EFFUSIONS, THEIR DIAGNOSIS AND TREATMENT.

DR. E. B. MONTGOMERY, of Quincy, Ill., in this paper pointed out the importance of early diagnosis, and, as a means of deciding doubtful cases, in addition to auscultation and percussion, needling, not only once, but repeatedly, if necessary. The use of sodium salicylate was advised as a medical treatment of small serous effusions, to be followed by aspiration if the fluid did not disappear in ten days or two weeks. For empyema the importance of a bacteriological diagnosis of the character of the infection was urged as a preliminary to correct treatment. Some pneumococcus empyemas yielded readily after aspiration to injection of 2 oz. of 2% formalin-glycerin. Others required intercostal incision and continuous drainage by one of the various types of drainage tubes, rib resection being rarely called for. To hasten the cure of small empyematous cavities and fistulæ, attention was called to the value of injections of Beck's 33% bismuth-vaseline paste.

### ETIOLOGY OF THE FUNCTIONAL NEUROSES.

DR. ELEANORA S. EVERHARD and DR. GERTRUDE FELKER, of Dayton, Ohio, contributed a joint paper on this subject in which they drew the following conclusions: (1) That the common element in the attributed causes of the functional neuroses was to be found

in the fact that the mental processes were not directed; therefore, the patient was the victim of any stimulus which chance might keep before the mind, and that there was no limit to the destruction of efficiency which might result. (2) That those symptoms commonly called nervousness were worthy of serious consideration because they indicated some degree of lack of control of nerve processes. (3) That self-indulgence by training the mind to follow the lines of least resistance predisposed to these neuroses. (4) That the value of living in accord with the laws of hygiene could not be overestimated, both because of its influence upon nutrition and because it required a measure of self-control, but that alone was insufficient. (5) That conditions of life which demanded of the individual in his vocation or avocation, less exercise of attention and will than he was capable of enduring without fatigue, bore to his nervous system the same relation that lack of muscular exercise bore to his muscular system. (6) That intelligent education at any age was effective, but since the ideal was prevention, the habit of directing mental processes should be established early.

Dr. Charles F. Read, of Hospital, Ill., spoke of the psychic factors in the causation of certain functional psychoses, and presented clinical studies.

Dr. Liston H. Montgomery, of Chicago, read a paper in which he spoke of the rôle of the physician, philanthropist, publicist and politician, regarding a federal department of health. He said that when a national department of health was established it would be capable of rendering the greatest amount of good to the greatest number of happy people, and thereby the prospects of longevity of man, ideal citizenship and posterity would be greatly enhanced, for which the medical profession would stand as sponsor.

### STANDARDIZATION OF BACTERINS.

Dr. Roswell T. Pettit, of Ottawa, Ill., spoke of the value of bacterin therapy as a general aid to local treatment in certain types of bacterial infections which was at the present time pretty well established. In the preparation of vaccines he did not try to estimate the number of bacteria present in a given volume. He took up a twenty-four-hour blood agar growth of streptococci in a definite amount of salt solution, shook thoroughly, centrifuged to throw down the clumps, put in a bottle specially prepared and killed by heat or carbolic acid. Then he made a one-tenth of one-hundredth dilution of this full emulsion and gave an initial dose of 5 ccm. of the one-hundredth dilution. This induced very little or no reaction. The dosage was then increased up through the one-tenth dilution and full emulsion to the point of local reaction. Then he proceeded very slowly, keeping in mind that the reaction induced and results obtained were the true indices of dosage. The reaction to be aimed at was a slight or moderate local reaction, an area of redness about the size of a dollar, without the localizing or general phenomena. By using increasing doses up through a series of dilutions this could be procured with a fair degree of accuracy, and an estimation of the number of bacteria used was entirely superfluous. The full emulsion could be called 100%, and 10% and 1% dilution of this full emulsion made. The doses could be recorded as 1, 2, 5, 7, ccm. etc., of the 1%, 10% or 100% emulsions. The advantages of a dilution method of estimating bacterial suspensions over a numerical were several. (1) The reaction, the real index of dosage, was relied upon and the empirical administration of bacterins was made less possible. (2) An index of antibody production was aimed at. (3) By using this method vaccines could be prepared with much greater rapidity, at least an hour was saved on each bacterin prepared, and if bacterins proved to be of value in acute infections, and the recent work of Dr. Rosenow, of Chicago, on artificial immunization in pneumonia seemed to point to this direction, the time saved would be a very important factor.

Dr. Nathan Rosewater, of Cleveland, Ohio, read a paper in which he pointed out the non-operative treatment of the prolapsed and dilated stomach and abdominal viscera.

### TREATMENT OF PERNICIOUS ANEMIA ASSOCIATED WITH ACHYLIA GASTRICA.

Dr. Alfred C. Croftan, of Chicago, submitted a clinical report in regard to the treatment of a certain group of pernicious anemia cases and described three cases that had been improved rapidly and have remained symptomatically well, without remissions, until the present date. The one constant factor observed in the cases of pernicious anemia observed during a period of years that were not distinctly attributed to the effect of syphilis, carcinoma, parasites or profound and continuous loss of blood was a lack of hydrochloric acid from the stomach contents, associated with a variety of digestive disturbances, allied with varying degrees of chronic undernutrition. That all cases of hyperchlorhydria and all cases of chronic undernutrition did not develop pernicious anemia called for the inclusion of some specific factor or factors hitherto unknown. At all events, the supplying of large quantities of hydrochloric acid together with abundant proteids by mouth and by rectum seemed a favorable point of attack and was persistently carried through with gratifying results. The dosage, technic of proteid, overfeeding and the general hospital management of such cases were described in full. From the results obtained the conclusion was drawn that a trial of this plan in this group of cases was decidedly worth while and seemed to produce results not otherwise obtainable by any means so far described.

### THE DIAGNOSIS OF TRIFACIAL NEURALGIA.

Dr. Hugh T. Patrick, of Chicago, stated in the vast majority of cases the diagnosis of the tic douloureux should be easy and certain as the traits of the disease were few and striking. But the author had had quite a number of other disorders referred to him as trifacial neuralgia. The most frequent had been migraine and sinus disease. Others were syphilis, brain tumor, alveolar abscess and other dental disease, nasal disease, herpes zoster, neurasthenia and lesion of the optic thalamus.

The pain of trifacial neuralgia was practically unique. There was nothing else just like it. It was short and sharp, in the beginning only a flash or jab or shot. The interval might be anywhere from a second or two to weeks or months. In the fully developed disorder the paroxysms might last a minute or two and the free intervals be so short that the pain seemed continuous. It never really was so. Nearly every patient had intermissions of weeks, months or even years during which he was entirely free from pain. One of the most striking peculiarities of the affection was that the paroxysms or jabs of pain were started by slight peripheral irritation, such as washing the face, using a handkerchief, stroking the mustache or the touch of a glass to the lips. He thought that the automatic act of winking often acted as an excitant. Such slight sensory stimulus in the area of one division of the nerve might occasion pain in another division. For instance, touching the lower lip might start a pain not in this region, but in the supra-orbital area.

### WATER THE MAIN FACTOR IN THE PREVENTION OF DISEASE.

DR. J. C. MINOR, of Hot Springs, Ark., stated the significant points in his paper were: First, nutrition and elimination were the main factors in maintaining health, but of the two, elimination was absolutely necessary and must be continuous and invariably performed equally by the sewers of the body. There was little or no vicarious action in the emunction of health and disease. You could not flush sewers without water, and if regular flushing was to be had, the water must be furnished the body regularly, and the purer the better. Second, normal resisting power prevented invasion of any and all diseases. Normal resisting power depended upon normal distribution of food, normal lubrication of all body structures and normal excretion of all waste products. Third, unless food be distributed to the system properly it would become a detriment instead of help to the system. It could not be distributed to the system properly without the proper amount of water taken in at the proper time. The stomach was the kitchen in which pabulum was prepared for the system. The small intestine was the table from which the system was served. The system would be served with only just enough, the remainder of the ingesta was thrown through the cecal valve into the sewer. If food was badly digested, the system rejected it. If food be more than the system required, the surplus was also rejected. All the rejected food was an irritant to the cecal region and its continuity. May it not be a cause for appendicitis? Fourth, there was a proper time for taking the proper amount of water. One's judgment should govern the measure of water to be taken with food. To take too much water just before, during or just after a meal would, so to speak, be to put the fire in the kitchen out, while not enough fluid would compel the stomach to borrow too heavily from the systemic volume. The one would retard digestion, and the other would give imperfect digestion.

### THE GRADUAL EVOLUTION OF A SANE THERAPY IN TUBERCULOSIS.

DR. F. M. POTTENGER, of Monrovia, Cal., contributed a paper on this subject. Among other things he said: The position of the sanatorium in the rational treatment of tuberculosis was very important. If the sanatorium was conducted on the proper lines, it afforded the best circumstances under which the known measures which had influence in building up and curing the patient might be applied. The home treatment, however, was one of the greatest boons to tuberculous patients because most patients were not able to be treated in sanatoria and must be treated in their own homes. The true position of home treatment, however, could be readily understood by the fact that it was an attempt to apply sanatorium régime and sanatorium conditions to the home.

### INTESTINAL SURGERY WITH A DEMONSTRATION OF A A NEW METHOD OF SUTURING THE BOWEL.

DR. A. E. BENJAMIN, of Minneapolis, Minn., stated the various instruments and appliances formerly used to facilitate the surgeon in his work upon the intestines had about all been discarded for the simple but efficient method of intestinal anastomosis by thread and needle. The work should be carefully but rapidly performed, which was often the case where the surgeon had from practice or experimental work upon the lower animals become skillful in the use of needle and thread. A positive blood supply to the tissues making up the anastomosis was necessary. The end-to-end method was not so certain; therefore the side-to-side anastomosis should be chosen when convenient. The evolution of the intestinal suture had brought them to the point where they were certain of good results, when the sutures were properly applied and were of the right material. Non-absorbable suture material should be cast off into the lumen of the intestine after serving its period of usefulness, and this was best accomplished when used for the inner layer. There was then less destruction of tissue. When placed externally it produced unnecessary adhesions, plastic exudate and fibrous bands. It might interfere with proper bowel function, because of its prolonged irritation. Absorbable suture material used for the outer layer was soon taken care of and did not cripple the action of the intestine. The application of the suture in the intestinal work had been carefully studied. It must serve the purposes of controlling hemorrhage, proper coaptation of the tissues, security against leakage, must avoid pursing, be quickly introduced and not strangulate the tissue. The back lock-stitch of Pagenstecher's thread as applied by the author for the inner layer served all these purposes. Experimental work had demonstrated that chromic catgut lasted sufficiently long when employed as the outer suture for positive and firm union to occur. The after-treatment of cases of suturing the bowel should be carefully supervised by limiting the diet, starvation treatment, if necessary, until the union was sufficiently strong before it became necessary for the bowels to be called upon to pass their contents onward. A perfect, clean and satisfactory result was obtained with the inner Pagenstecher lock-stich, and a chromic catgut for the outer in intestinal anastomosis.

### THE RÔLE OF THE BACILLUS COLI COMMUNIS IN ACUTE AND CHRONIC DILATATION OF THE STOMACH.

DR. FENTON B. TURCK, Chicago, presented some facts with reference to the rôle of the bacillus coli in the gastro-intestinal tract in producing lesions in the liver, kidney, stomach and other organs. Experiments were begun with intravenous and intraperitoneal injections into dogs, rabbits, guinea pigs and rats. The results obtained were variable and inconstant. On feeding animals with bouillon cultures of the bacillus coli daily over a period ranging from three to fourteen months, lesions were found in the stomach, duodenum, liver, kidney, brain and spinal cord, varying according to the methods, quantity and character of culture. It was found that animals fed with cultures of bacillus coli would acquire acute or chronic dilatation of the stomach by overworking or overloading that organ. Examination of the blood showed that it remained sterile during the experiments, and the heart's blood at death was also sterile. In feeding cultures of the colon bacillus, pronounced changes were revealed in the blood and tissues. Agglutination of bacillus coli by the dog's serum was noted, hemolysis of the blood was evident; cytolysis and autocytolysis of the cells of the mucous membrane of the stomach, kidney, liver and other organs were marked on microscopic examination. The picture was not one of resection to an infection, but rather a systemic condition of induced cellular change. To obtain spontaneous acute or chronic dilatation of the stomach in animals, it is necessary to first feed the animals with cultures of bacillus coli over a long period of time, followed by over-use of the stomach, especially increasing the intragastric pressure. Acute and chronic dilatation of the stomach was due to the fatigue of the gastric muscles.

The author pointed out the indications for treatment in acute dilatation of the stomach.

The usual methods of treatment were gastric lavage; diet, frequent but light meals; drugs, such as tonics, laxatives, alkalies, or acid, as indicated; electricity and exercise; hydrotherapy, balneology, rest and recreation. In case of failure of the above methods, surgical operation was indicated.

For the last seventeen years he had followed these indications and methods: (1) Reduce the fatigue of the gastric muscle by rest, followed by appropriate exercise of the gastric muscle, inducing normal peristalsis. (2) Sterilization, as far as possible, of the gastro-intestinal tract. (3) Restore the integrity of the splanchnic circulation.

OFFICERS.

The following officers were elected: President, Dr. Robert H. Babcock, Chicago; Vice-Presidents, Drs. Arthur D. Holmes, Detroit, and Charles E. Barnett, Fort Wayne, Ind.; Secretary, Dr. Henry Enos Tuley, Louisville (re-elected); and Treasurer, Dr. S. C. Stanton, Chicago (re-elected).

The selection of the place of meeting and of the chairman of the Committee of Arrangements for 1911 was left to the Executive Committee with power to act.

## Book Reviews.

*The Non-Surgical Treatment of Duodenal Ulcer.* By GEORGE HERSCHELL, M.D. (Lond.). London: Henry J. Glaisher. 1910.

This publication is the reprint of an article by the author which originally appeared in the *Clinical Journal*, and states rather categorically his views on the medical treatment of duodenal ulcer. He believes this condition usually due to pyorrhea alveolaris, to intestinal auto-intoxication, or to anemia. Its rational treatment, therefore, he bases on the removal of these causes by remedying deficiencies in the blood, by disinfecting the intestinal tract and by reducing the acidity and peptic power of the gastric juice. This third end he attempts by the administration of alkalies and bismuth and of bland, tasteless panada, preceded by several days of rectal feeding. He also gives injections of fibrolysin for any adhesions which may be present. He requires the patient to remain in bed three weeks under this regimen. To avert recurrence, he recommends the subsequent wearing of an abdominal support to prevent traction on the mesentery, and a dose of normal horse-serum daily for a month, then twice a week for another month. His method seems logical and deserving of trial and observation.

*A Text-Book of General Bacteriology.* By EDWIN I. JORDAN, Ph.D. Fully illustrated. Second edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1910.

This second edition of a well-known general textbook on bacteriology adds to the original several new sections on the most recent progress in the science. Without being elementary, the work is introductory rather than advanced in character and aims especially to emphasize the relations of bacteriology to various professional and human interests. Besides the descriptive bacteriology, there are chapters on immunity, on the bacterial diseases of plants, on the pathogenic trichomycetes and protozoa, and an appendix on infectious diseases of unknown causation. The illustrations are many and excellent. The volume is a useful general treatise on the subject rather than a laboratory manual, and should be of interest to general readers as well as of value to medical and other students.

*A Manual of Midwifery.* By HENRY JELLETT, B.A., M.D., Dublin University, with the assistance in special subjects of W. D. DAWSON, M.D.; H. C. DRURY, M.D.; T. G. MOORHEAD, M.D.; R. J. ROWLETTE, M.D. Second edition. Seventeen plates, 557 illustrations in the text. New York: William Wood & Co. 1910.

Dr. Jellett and his co-writers are to be congratulated upon the appearance of the second edition of their work on obstetrics. Every chapter shows painstaking care. The text is clear and the illustrations excellent. The book covers the usual field of obstetrical textbooks, the chapters on mechanism of labor and on contracted pelves being especially good. It is to be regretted that Dr. Jellett has adopted the non-descriptive nomenclature of first, second, third and fourth positions of the various presentations, thereby doing away with the uniform nomenclature which is most helpful to students. There are many little differences in procedure which are entirely unnecessary to comment upon in a book of this character and authority. It has been a pleasure to read and study this book, and we hope that it will have a wide sale in America.

*A Manual of Obstetrics.* By A. F. A. KING, A.M., M.D., LL.D., Professor of Obstetrics in the Medical Department of the George Washington University and in the University of Vermont. Eleventh edition, revised and enlarged. Three hundred and forty-one illustrations in text, 3 plates. Philadelphia and New York: Lea & Febiger. 1910.

One hesitates to criticise a book that has come to its eleventh edition, but there are many points in this book which do not conform to the best obstetrical teaching of the present time. The illustrations are crude and old and in many cases insufficient. The author's treatment of artifical feeding, the premature baby, nursing and weaning are most superficial and would give every pediatrist the right to say, as one prominent one has, that few obstetricians are able to look after the average feeding of a baby.

*A Textbook of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease.* By ARTHUR R. CUSHNY, M.A., M.D., F.R.S., Professor of Pharmacology in the University of London; Examiner in the Universities of

London, Manchester, Oxford and Leeds; formerly Professor of Materia Medica and Therapeutics in the University of Michigan. Octavo, 744 pages, with 61 engravings. Philadelphia and New York: Lea & Febiger. 1910.

In this new edition, the author has kept up the standard of the work as one of the best books on pharmacology in the English language. The book has been thoroughly revised and most of the new researches on pharmacology have been considered. We note, however, that in a number of instances the author, in spite of recording the newer investigations, fails to change sufficiently his text accordingly. We were pleased to see the introduction of a chapter on antitoxins, as these agents are definitely pharmacological and have usually received too little attention on the part of pharmacologists.

*Report of the (New South Wales) Government Bureau of Microbiology.* Sydney: William Applegate Gullick. 1910.

This first annual report of the new South Wales Bureau of Microbiology represents the results of its first year of work since its establishment as a separate branch of the reorganized Department of Agriculture. Its function was intended to be especially "to deal with questions concerning the parasitic and microbic diseases of plants and of stock, and with various farming problems." The work of the laboratory has been divided into two parts: first, routine examination of dairy products, plants, rats and human pathologic material; second, research in the bacterial, fungoid and protozoan diseases of animals and plants, in hygiene, sanitary and economic problems, and in the bacteriology of soils. The report presents a vast amount of data which may become the basis of much future study and profitable application. It is interesting to note that the report speaks very hopefully of the possibilities and value of antityphoid inoculation, citing the fact that of 6,866 imperial troops exposed to typhoid infection, the percentage of incidence among the inoculated was only 3.7, and among the uninoculated, 32.8. Such figures are eloquent.

*A Manual of Nursing.* By MARGARET FRANCES DONAHOE. Illustrated. New York and London: D. Appleton & Co. 1910.

This volume represents the results of the author's experience as a pupil at the Massachusetts General Hospital, and as superintendent of nurses and principal of the training school at the Philadelphia General Hospital. It consists of a series of chapters on selected topics in nursing, practical and well written, though rather sparely illustrated. It should be a useful addition to the library of graduate as well as of pupil nurses.

*Bacteriology and Surgical Technic for Nurses.* By EMILY M. A. STONEY. Third edition, thoroughly revised and enlarged by FREDERIC RICHARDSON GRIFFITH, M.D. (University of Pennsylvania), of New York. Illustrated. Philadelphia and London: W. B. Saunders Company. 1910.

Miss Stoney's textbooks on nursing are of recognized and standard merit. This new edition of the present volume contains the material of the original, with the addition of some diet recipes, more detailed description of certain operations and a brief glossary. The illustrations are numerous and excellent. The book logically presents the relations of bacteriology to surgical diseases and nursing.

*The Hygiene of Infancy and Childhood and the Underlying Factors of Disease.* By A. DINGWALL FORDYCE, M.D., F.R.C.P. (Edin.), Extra Physician, Royal Hospital for Sick Children, Edinburgh; author of "Diet in Infancy." Pp. 290. New York: William Wood & Co. 1910.

The author has endeavored in this book to correlate the primary scientific facts of medicine as they apply to pediatrics and to combine in one volume various aspects of pediatric medicine which can only be found otherwise by wide reading. He divides the factors which have to do with the development of the child, whether normal or abnormal, and with the causation of disease in childhood, into five, namely, food, heredity, environment, bacterial and age-period. An immense amount of material is considered, some of it in considerable detail, some very superficially. His conclusions are, in general, very reasonable and in accord with the most recent investigations. Much of the text is in quotation marks. We think that the book would have been more satisfactory if the author had given us his own opinions in his own words. The book will, on the whole, repay perusal.

*A Textbook of Bacteriology.* By PHILIP HANSON HISS, JR., M.D., and HANS ZINSSER, M.D. With 156 illustrations in the text, some of which are colored. New York and London: D. Appleton & Co. 1910.

The sub-title of this volume declares it to be "a practical treatise for students and practitioners of medicine." It is divided into five sections dealing respectively with bacterial biology and bacteriologic technic, with infection and immunity, with description of the pathogenic micro-organisms, with diseases of unknown etiology (rabies, smallpox, poliomyelitis, yellow fever, measles, scarlet fever and foot-and-mouth disease), and with the bacteria of the air, the soil, water and milk. Its scope is thus extensive and its intent scientific rather than popular. It is not, however, unduly technical. Of greatest interest, perhaps, are the chapters dealing with the nature and theories of infection, immunity, phagocytosis and anaphylaxis, with the various antibodies and with the general principles and technic of serology. Representing as it does the experience of its authors as teachers and investigators, the book should prove of authoritative merit and of recognized value to the profession.

THE BOSTON

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 2, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 809 Paddock Building, 101 Tremont Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.*

*Remittance should be made by money order, draft or registered letter payable to*

101 TREMONT STREET, BOSTON, MASS.

## INACCURACY OF VITAL STATISTICS IN THE UNITED STATES.

IN an editorial on the "Responsibility of Physicians for Vital Statistics," on page 29 of the issue of the JOURNAL for Jan. 5, we commented on "the importance of reliable vital statistics as a basis not only for scientific research, but also for the hygienic and sanitary measures of preventive medicine and for many sociologic reforms." A bulletin just issued from Washington, D. C., by the Bureau of the Census of the United States Department of Commerce and Labor, reiterates this statement, and directs further attention to the inadequacy and unreliability of such statistics in many parts of our country. The death registration area of the United States now comprises only about 55% of the total population, the birth registration area is smaller, and even within these areas the records are often incomplete and inaccurate. No foreign nation of equal claim to civilization is as deficient in this respect as the United States.

Of the degree of reliability of such vital statistics as we have, it is harder to form a just estimate. In the December, 1910, issue of *Assurance*, a New York publication devoted to the problems and interests of life insurance, appeared a somewhat polemic article by Lawrence Irwell, of Chicago, criticising certain statements and figures in Professor Fisher's "Report on National Vitality" and his paper on "The Costs of Tuberculosis in the United States and Their Reduction," both recently published in bulletins of the Committee of One Hundred on National Health. The essence of Mr. Irwell's contention is that the decline in mortality from tuberculosis in this country and in others, which Professor Fisher attributes "to the growing use of hospitals . . . and of our recently acquired knowledge of the efficacy of fresh air and the outdoor life," had really begun some decades before Koch's discovery of the tubercle bacillus, and has been due less to artificial human agencies than to the great process of natural selection. Furthermore, Mr. Irwell maintains that many of the statistics which Professor Fisher employs to prove his points are unreliable and misleading, owing to inaccuracies in registration above alluded to. Mr. Irwell analyzes some of these statistics and points out their fallacies. His conclusion is that the decline in mortality from tuberculosis throughout the world in the past thirty years is not nearly as great as has been maintained, and that what decline has occurred has taken place rather from natural causes than from the efforts of preventive medicine.

Whatever the respective merits of the conflicting opinions of Professor Fisher and Mr. Irwell, which could be determined only by much more extensive examination of available data, the case in point is an illustration of the uncertainties involved in vital statistics and their interpretation, and of the extreme caution which should be observed in making or accepting any conclusions deduced from them. Such conclusions can become reliable only when the figures from which they are drawn become so. The bulletin of the Census Bureau, to which we earlier referred, closes with these appropriate words on the subject:

"The accurate collection, tabulation and analysis of records of births, deaths, stillbirths, marriages, divorces and sickness may be said to constitute the bookkeeping of humanity. It is fundamental to the practical application of hygiene to secure higher efficiency, longer duration of life and fuller measure of happiness."

## PROTECTION OF INFANTS AND CHILDREN.

THE strong tendency toward prophylactic medicine is nowhere better exemplified than in the various efforts being made toward the better care of children and infants. The general controversy which has been going on in New York over milk depots has apparently finally been settled in favor of the continuance of such rational means of averting infant mortality. The plan, inaugurated in connection with tuberculosis, of popular exhibits also finds a place in connection with the work for children, as illustrated by the recently opened New York Child Welfare Exhibit, which is to be continued until Feb. 12, with

a special program for each day. The design is to present a complete and comprehensive exposition of the influences which affect the life of the city child for good or for evil and to demonstrate the economy of concentrating efforts for human betterment upon the children of the present time and so of lessening the social waste and financial burden of charities and reformatories in the future. At the opening exercises addresses were made by Robert W. DeForest, of the Sage Foundation, and others, and there was singing by a chorus of one thousand public school children. The exhibits are on the general plan of the tenement-house and tuberculosis exhibitions held previously in the city, and each day conferences on presented subjects are held by physicians, educators, social workers and municipal representatives. A large central court provides exhibition space for motion pictures, and for the folk-dancing, gymnastic excercises, and musical, song and play festivals in which 3,000 children take part, while the surrounding galleries accommodate 2,000 spectators. More specifically the purposes of the exhibit are: (1) To show the work of all agencies now striving for the child's welfare and to encourage their correlation, improvement and extension. (2) To throw light on forms of city life detrimental to the child, and to suggest definite remedies for these conditions. (3) To stimulate the formation of some complete program of action dealing with all the needs of the city child.

The committee on infant mortality of the New York Milk Committee held an open meeting at the Hotel Plaza, on Jan. 16, to further the movement undertaken by the committee to obtain an annual fund of $300,000 for the purpose of maintaining sixty additional infants' milk depots, each with physicians and trained nurses in attendance. Controller Pendergast presided, and addresses were made by Dr. Abraham Jacobi; Wilbur C. Phillips, secretary of the New York Milk Committee; Mrs. J. Borden Harriman, vice-chairman of the Committee on Infant Mortality, and others. Mr. Pendergast stated that the city government was in complete sympathy with the movement, citing the recent appropriation of $40,000 by the Board of Estimate for the establishment of milk depots as an evidence of this. He believed, however, that the city should finance only a part of the work, and that the rest should be undertaken by the citizens. Dr. Jacobi was emphatic in his endorsement of the work done by the milk depots, not only in furnishing good milk for infants, but for the educational value of the instructions of the physicians and nurses. He also emphasized the need of complete co-operation among those interested in this work, believing that such co-operation would mean the saving of the lives of thousands of children. Mr. Phillips showed how the money was spent and what was accomplished. At the close of his remarks pictures were thrown on a screen illustrating the work of the milk depots. Mrs. Harriman explained how the city had been districted and appeals for financial help sent out, how the plan undertaken had been approved by the best informed social workers and child specialists in the medical world, and how the work was related to the Health Department.

## LIFE INSURANCE AND PREVENTIVE MEDICINE.

THE recently published proceedings of the fourth annual meeting of the Association of Life Insurance Presidents, held in Chicago on Dec. 9 and 10, 1910, contains many interesting addresses dealing with various aspects of the important and growing work of life insurance in modern civilization. Of particular pertinence are the papers in the section on "Life Extension Work." It is, of course, to the pecuniary interest of insurance companies that their policy holders should live as long and as healthfully as possible, and for this economic reason they have somewhat unexpectedly become valuable allies of the medical profession and efficient practical workers in the field of preventive medicine. In his address before the association on "The Fight against Preventable Diseases," Dr. Eugene H. Porter, New York State Health Commissioner, after reviewing the statistics of death from such diseases, outlined the methods and details of the work which has been and may be done in this conflict by the insurance companies, whose size, capital and organization give them an almost unequalled power of usefulness. In a paper on "Modern Sanitation," Dr. Alvah H. Doty, health officer of the port of New York, described other valuable recognized methods of disease prevention by sanitation, whose establishment and enforcement may be fostered by the companies. Dr. Cressy L. Wilbur, chief statistician of the United States Census Bureau, spoke on "The Work of the Census in Vital Statistics," and emphasized the importance of uniform and complete accuracy in the registration of such statistics as a prerequisite for the study and prevention of disease and needless mortality. The machinery of life

insurance affords admirable means for the accumulation and preservation of such essential data. These papers and others illustrate admirably the possibilities of co-ordination between the work of preventive medicine and that of the insurance companies, agents whose economic and material strength the profession should be glad to enlist in its unceasing conflict with disease and death.

## REPORT AND RECOMMENDATIONS OF THE MASSACHUSETTS MILK COMMITTEE.

At the time of the "milk strike" in Boston last spring, a committee of five was appointed by the state legislature to investigate and report on the inspection of milk in Massachusetts. This committee consisted of the three members of the State Dairy Bureau, of Dr. Milton J. Rosenau, professor of preventive medicine and hygiene at the Harvard Medical School, and of Mr. George H. Ellis, a milk producer of Boston. The committee has just presented its report, with a bill embodying the provisions which it suggests. This proposed bill empowers the State Board of Trade "to make reasonable regulations regarding the sale of milk, its production, transportation and keeping"; requires that all milk dealers shall be licensed and their places of business regularly inspected, and provides for the "establishment of a milk division under control of the State Board of Health, with a chief, an assistant chief, a chief inspector and not more than twenty assistant inspectors," and authorizes the expenditure of not more than $100,000 annually for the salaries and expenses of this division.

The members of the milk committee are unanimous in their agreement that the present system of inspection is inadequate and involves much unnecessary expense and duplication of work without guarantee of security. They are also unanimous in recommending uniform inspection and control by state authority; but three of the members believe that it should be administered by a joint committee of the Dairy Bureau and the State Board of Health, whereas the other two believe that the authority and responsibility should rest solely with the Board of Health.

The bill proposed in the report of the milk committee presents a plan alternative with that of the bill already introduced before the State Senate, to which we made reference in the issue of the JOURNAL for Jan. 19. The bill recommended by the committee has apparently the advantages of providing centralised authority; of establishing a uniform system of inspection without complicated machinery or liability of conflict and of representing the opinion of experts who have given the matter careful investigation. Legislative discussion should determine the respective merits of the two measures and lead to the enactment of such laws as shall afford the greatest security to all communities in the state.

## THE FUTURE OF HUMAN LACTATION.

At a meeting of the Milk and Baby Hygiene Association of Boston, held on Jan. 23 in this city, addresses outlining the policy and describing the work of the association were made by the newly elected president, Mr. Charles W. Eliot; by the outgoing president, Mr. George H. Ellis; by the director, Mr. Walter E. Kruesi; by the medical director, Dr. Arthur A. Howard, and by Mr. John Spargo. Some of Mr. Spargo's remarks were particularly interesting, in that he seemed to suggest the possible ultimate cessation of the lactating function in woman as a slow result of social and physical evolution. Without concurring in this prophecy, it must be admitted, from certain obstetric and pediatric experiences, that it has some plausibility and that in the course of the ages the time may come when the human infant will be from birth, to use Mr. Spargo's phrase, "a parasite on the cow." This would be a condition not without biologic parallels.

## ISOLATION OF DIPHTHERIA CARRIERS IN CHICAGO.

It is reported from Chicago that the detection and quarantine of diphtheria carriers among schoolchildren is to be undertaken by the board of health in that city as a possible means of reducing the incidence of the disease. The considerable number of such "carriers" among children apparently well was indicated by the series of cultural experiments conducted by the Board of Health in Boston over a year ago. At the same time the difficulty and probable opposition to be encountered in an effort to quarantine them were considered for the present too great to justify the attempt. The experiment in Chicago, whether successful or not, should be of value, and its result should prove a useful contribution to medical experience.

In this connection it is interesting to note an article by Dr. Henry Page, of Manila, P. I., in the January number of *The Archives of Internal Medicine* on "Diphtheria Bacillus-Carriers." Dr.

Page summarises his studies of carriers, and reports a case in which was successfully employed a method of treatment first suggested by Schiotz, of Copenhagen, namely, spraying the throat with pure cultures of staphylococcus aureus, which in this case and in six reported by Schiotz was followed by disappearance of the Klebs-Loeffler bacilli in two or three days. The merits of this treatment deserve further investigation and consideration by the profession.

## THE DUST NUISANCE IN THE STREET AND THE HOUSE.

NOTHING further seems to be heard nowadays about the campaign against promiscuous expectoration in Boston. Its place in popular interest has apparently been taken by the agitation against the dry sweeping of streets, a practice long recognized by physicians as abominable, but recently brought into public prominence by various interviews on the subject published in the daily press. There can be no doubt that clouds of dust, whether stirred up by sweeping or by the wind, are a disagreeable and dangerous irritant to the respiratory tract and predispose it to infection by various organisms. It is probable that city dust also disseminates numerous pathogenic bacteria, notably those of tuberculosis. The great increase of colds, influenza, pneumonia and other respiratory infections during dry, windy weather when there is no snow on the ground is evidence in the experience of every medical practitioner that dust is a factor in their production. Various methods have been suggested to check the dust nuisance, such as sprinkling the streets with oil or with calcium chloride solution, sweeping them wet instead of dry, and hooding the sweepers with canvas covers. Popular discussion of the problem is likely to produce some good. Incidentally it would be still better if this campaign, carried into the home, should lead to the abolition of that pernicious domestic fallacy, sweeping-day, which still survives to be the curse of many a New England household.

## MEDICAL NOTES.

A SUSPECTED LEPER IN WASHINGTON. — Report from Washington, D. C., states that a young Filipino, who came to this country from the Philippines a year ago, is now held in quarantine at the United States Naval Medical School Hospital under suspicion of having leprosy. He has been employed as a servant in the family of a naval officer.

APPOINTMENT OF DR. HUMBERT. — It is reported that Dr. Eugene P. Humbert, of the Bureau of Plant Industry of the United States Department of Agriculture, at Washington, D. C., has been appointed associate biologist in the University of Maine Experiment Station. He is a graduate of the Iowa Agricultural College.

CHOLERA IN ARABIA. — Report from Hodeida, Arabia, describes the recent outbreak there of Asiatic cholera among the natives and among the Turkish recruits sent as reinforcements to the troops now fighting rebellious Arabs in the Yemen district. Hodeida is a base of supplies and munitions, and there is fear of the spread thence of a general epidemic through the army in the field.

SUCCESSFUL UNION OF MEDICAL SCHOOLS IN CINCINNATI. — The reorganised Medical College of the University of Cincinnati has just completed successfully its second year since its union with Miami Medical College. The new institution is now closely affiliated with the Cincinnati City Hospital, in which many of its professors and instructors hold clinical and laboratory appointments.

PROPOSED BREAD STANDARD IN GREAT BRITAIN. — Eight physicians in London, including Sir Alfred Fripp, are said to have issued recently a statement advocating the establishment in England of a legal standard for the nutritive value of bread, similar to the percentage standard already existing for milk. They recommend the requirement that all bread shall be made "of unadulterated wheat flour, containing at least 80% of whole wheat."

THERAPEUTIC POSSIBILITIES OF MESOTHORIUM. — Report from London announces the discovery by Prof. Ernest Rutherford, director of the physical laboratory at the Univerrity of Manchester, of a new method of extracting mesothorium from thorium. Mesothorium is a disintegration product of thorium, and stands midway between it and radiothorium. The possible medical importance of this discovery is that mesothorium, which is alleged to possess radio-active properties, is much cheaper than radium and may conceivably become of use as a substitute for it in therapeutics.

THE PLAGUE IN THE FAR EAST. — Reports from the far East indicate that the epidemic of bubonic plague is steadily extending. In Manchuria, its original focus, the fatalities are most

numerous. In Fudsiadian there are said to have been 1,500 deaths during the week ending Jan. 23. The infection has invaded Pekin, where there were 10 deaths from it in the same period. The port of Tientsin, a great wool-shipping center, has been closed. It is reported that the plague has also appeared in Amoy, and that one death from it has occurred at Pogranitchnaia, near Vladivostock, in Russia. The disease is said to be pneumonic in type and of extremely fatal virulence.

Sewage and Seawater. — In a recent paper before the British Royal Sanitary Institute, Dr. Edward Newton called attention to the increasing pollution of seawater along the coasts of Great Britain and France by sewage from the great maritime cities. Bacteriologic examinations which he has made indicate that in many places the sea is contaminated in this manner to a distance of twenty-five miles from land. Probably this condition is not so serious as the pollution of rivers, more common formerly than at present. There is a possibility, however, of the ultimate necessity of the disinfection of sewage from seaport towns, whose excreta may prove too much for

> "The moving waters at their priestlike task
> Of pure ablution round earth's human shores."

Two More Seizures of Opium. — Two large seizures of opium have been made in the United States during the past week. At San Francisco, on Jan. 25, the United States customs officers seized three hundred tins of opium, worth $12,000, after a running fight with two men who were attempting to land it in a small boat from the steamer *Korea*, which arrived in port from the Orient a fortnight previously. The smugglers escaped.

In New York City, on the evening of the same day, two Chinese "cigar stores" in the tenderloin district were raided by the police, with a resulting seizure of six hundred two-pound cans of opium prepared for smoking, and a considerable quantity of the crude drug, of a total value of $10,000. Four Chinamen on the premises were arrested, and held in $1,500 bail each, on a charge of violating the federal opium exclusion act.

## BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, Jan. 24, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 50, scarlatina 53, typhoid fever 3, measles 81, smallpox 0, tuberculosis 54.

The death-rate of the reported deaths for the week ending Jan. 24, 1911, was 20.74.

Boston Mortality Statistics. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Jan. 28, 1911, was 277, against 231 the corresponding week of last year, showing an increase of 46 deaths, and making the death-rate for the week, 20.97. Of this number 142 were males and 135 were females; 267 were white and 10 colored; 166 were born in the United States, 103 in foreign countries and 8 unknown; 51 were of American parentage, 187 of foreign parentage and 39 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 50 cases and 2 deaths; scarlatina, 50 cases and 1 death; typhoid fever, 5 cases and 1 death; measles, 79 cases and 3 deaths; tuberculosis, 76 cases and 25 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 37, whooping cough 4, heart disease 36, bronchitis 1. There were 16 deaths from violent causes. The number of children who died under one year was 46; the number under five years, 74. The number of persons who died over sixty years of age was 76. The deaths in public institutions were 108.

Death-Rate in Malden. — The annual report of the Malden (Mass.) Board of Health states that the death-rate in that city during the year 1910 was 13.6 per thousand.

A Living Centenarian. — Mrs. Laurena S. Lea, of Pittsfield, Mass., celebrated last week the supposed centennial anniversary of her birth. Her health is said to be excellent. She has one living daughter and eight grandchildren and great-grandchildren.

A Bill to Permit Unvaccinated Children to Attend the Public Schools. — A bill accompanying a petition to permit unvaccinated children to attend the public schools was given a hearing before the joint committee on Public Health of the Massachusetts Legislature on Tuesday, Jan. 31.

Fire at the Cushing Hospital. — A slight fire in the laundry of the Cushing Hospital, Roxbury, on Jan. 24, caused damage to the estimated amount of $1,500. A grass bonfire, set by boys, in an adjacent field was the cause, and for a time menaced also the Baptist and Charity Club hospitals.

FINE FOR ILLEGAL SALE OF BUTTERINE. — In the Newton District Court last week, a restaurant keeper of West Newton, Mass., was fined $10 for serving butterine to his customers without posting, as required by law, a notice of the fact that he was doing so.

A DOCTOR'S BEQUEST TO THE NASHUA HOSPITAL. — The will of the late Dr. George F. Wilber, of Nashua, N. H., whose death is noted in another column of this issue of the JOURNAL, was presented for probate on Jan. 27. It names as residuary legatee, the Nashua Emergency Hospital, which will probably receive about $60,000 from his estate.

REPORT OF THE DEACONESS HOSPITAL. — At the annual meeting of the New England Deaconess' Association, held in Boston on Jan. 24, the superintendent of the Deaconess' Hospital in Longwood reported that during the year 1910 1,051 patients were received into that institution. There were also reports of other charitable and philanthropic activities of the association.

RATIO OF MARRIAGES AND BIRTHS IN MASSACHUSETTS. — The annual report of the secretary of the Commonwealth of Massachusetts, published last week, contains, among interesting data, the returns of births, marriages and divorces in this state for 1909. During that year there were 1,931 more marriages and 231 more divorces, but 2,872 fewer births than in 1908. The medical and sociologic suggestions of these figures are obvious and in many respects depressing.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH. — A quarterly meeting of the Massachusetts Association of Boards of Health, held in Boston on Jan. 26, was attended by about one hundred members. Papers were presented on "Modern Board of Health Methods in a Small Town," "Modern Board of Health Methods in a Small City" and "The Relation of Illuminating Gas to Public Health." Dr. Henry P. Walcott, of Cambridge, Mass., was elected president of the Association for the ensuing year.

WORK OF THE MASSACHUSETTS HOMŒOPATHIC HOSPITAL. — At the annual meeting of the corporation of the Massachusetts Homœopathic Hospital, held in Boston last week, it was reported that during the past year 12,036 patients were treated in the out-patient department, 4,925 in the hospital wards, and 483 in the contagious department. During the year some permanent building improvements were made. The hospital also received from Mrs. Robert Dawson Evans a sum sufficient to erect a building, now under construction, for clinical research and the study of preventive medicine, with a fund of $100,000 for its permanent endowment. During 1910, 27 nurses graduated from the hospital training school and 46 probationers were admitted.

REPORT OF THE CHILDREN'S HOSPITAL. — The annual meeting of the managers of the Children's Hospital of Boston was held on Jan. 25. It was reported that during 1910 the number of patients admitted to the wards showed an increase of 61 over the previous year. The out-door relief has been reorganised under the name of the social service department, and its activities considerably extended. During the year, 2,125 visits were made by the three nurses in charge of this work. The receipt of bequests from various estates was acknowledged to the total of $44,613. It was announced that a sufficient sum of money has now been raised to warrant the erection of the proposed new buildings of the hospital on Longwood Avenue, and it is hoped that work on their construction may be begun during the coming spring.

### NEW YORK.

BONE AND JOINT SURGERY. — Dr. John B. Murphy, of Chicago, president of the American Medical Association, gave a special clinic at the New York Post-Graduate Medical School, Jan. 6, on "Bone and Joint Surgery."

BEQUESTS. — Among other bequests in the will of Mrs. Emily H. Moir, of New York, who died on Dec. 23, leaving an estate valued at $1,000,000, are $20,000 to the Presbyterian Hospital, $10,000 each to the New York Eye and Ear Infirmary, the Society of the Lying-In Hospital, the Minturn Hospital for Scarlet Fever and Diphtheria, and the Babies' Hospital of the City of New York, and $5,000 each to the Northern Dispensary and the Nursery and Child's Hospital. Of the residuary estate, one quarter goes to the Presbyterian Hospital and one twelfth (estimated at $60,000) each to Harvard and Princeton universities.

PRIORITY IN DEATH FROM ACCIDENT. — The important question, where property is involved, of deciding in cases where two persons of a family die from accidental causes almost at the same instant, is often a very difficult one. This is shown in the deaths of J. George Lafargue and his wife, Henrietta, who were killed by the

striking of their automobile by a railway train in August, 1906. In the Surrogate's Court it was decided, after prolonged medical and legal disputation, that the husband died first, but this decision was recently reversed by the Appellate Division of the New York Supreme Court. An appeal from this finding has been taken, and the issue will now have to be fought out again in the highest tribunal of the state, the Supreme Court. Both Mr. and Mrs. Lafargue left wills, and in each of these different sets of heirs were named.

10. Smith, L. L. *Report of a Case of Diphtheria of the Vulva in a Child Three Years of Age.*

7. Moschowits draws a striking comparison between the phenomena of experimental anaphylaxis and such diseases as asthma, hay fever and urticaria, and he suggests that these latter may be manifestations of an anaphylactic reaction in the human organism. The characteristic symptoms of "serum disease" are dyspnœa, cyanosis, urticaria and eosinophilia. This seems more than a coincidence and should stimulate research. [L. D. C.]

8. Sachs considers that the reactions occurring on application of tuberculin differ in their degree according to the various sites of the body selected as points of inoculation. The results of cutaneous tests performed with various dilutions of tuberculin would seem to indicate that the actual amount of absorbed tuberculin is a factor of importance in determining the degree of the reaction. Sufficient evidence has not been produced so far to substantiate the claim that a positive conjunctival reaction signifies active tuberculous disease.

9. Fordyce considers that two things which contribute to our failure to cure more cases of syphilis and to prevent the late or parasyphilitic stages are the tendency to regard syphilis as a mild infection and become lax in carrying out treatment and the lack of familiarity with the great possibilities of specific drugs. The old method of administering mercury internally in small doses over long periods of time is not only inefficient, but, in the light of recent developments, may be harmful in the possible cultivation of mercury-fast strains of spirochetes. The best results are obtained when the drug is administered by intramuscular injection or by inunction or by a combination of both. As regards salvarsan, except in a limited number of cases this drug in a single dose has not fulfilled its promise of a specific in human syphilis. It is, however, a most efficient agent in controlling the early manifestations of the disease and in limiting the contagious stage when mucous patches and condylomata are present. The result of one injection is fully equal to that of a prolonged course of mercury in the early stage and to a combination of mercury and KI in the later stage, with the advantage that we avoid the unpleasant effect of mercury. It is especially valuable in combating emergencies such as choked disk, in malignant syphilis or the hereditary type or in those cases resistant to mercury. Objections are the pain which immediately follows the injection and the possible injury to the sight. Intravenous injection obviates the first objection and will undoubtedly be the method of administration of the future. As to the impression that it is desirable to avoid mercury for a period before and after the giving of salvarsan, this is without foundation and, in fact, many patients do better when the two are given together. This supports Ehrlich's theory that the organism may have more than one chemoreceptor and can be attacked from more than one side. In cases in which a second dose of salvarsan does not seem advisable a course of mercury is then recommended. [E. H. R.]

5. Nichols was able to transfer the spirochetæ of yaws from man to the monkey and from the monkey through three generations in the rabbit. Wilson found only very trifling differences in the study of the morphology of the organisms in syphilis and yaws. He considers that the differences in the lesion of syphilis and yaws in the monkey is the surest way to differentiate the organisms. The lesions of syphilis and yaws in the rabbit differ only in degree. The complement-fixation reaction occurred in the rabbits infected with the spirochetæ of yaws as well as those infected with the spirochetæ of syphilis.

8. Duval was able to grow the bacillus of leprosy in pure culture and to reproduce the disease in the Japanese dancing mouse. He used a special medium of agar or banana, prepared with a 1% solution of cystein and tryptophane; after an incubation of from one to two months small white colonies appear if the cultures are kept in a moist temperature, ranging between 32 and 35° C. The cultures are not sealed as oxygen is constantly required in addition to moisture. Light also seemed to favor the growth of the bacillus of leprosy. [R. I. L.]

1. In their effort to find a correct method of standardizing disinfectants, Anderson and McClintic are doing the public a service. According to their paper, there has been no such method proposed; they criticise the Rideal-Walker and Lancet methods, and offer a substitute which, although based upon the same principle of comparison with phenol, does away with several sources of error. The "phenol co-efficient" of the disinfectant in question is determined by comparing its bactericidal power in certain dilutions with the bactericidal power of phenol in the same dilutions. The bacteria used, the time of exposure and the temperature of the media must, of course, be similar with both substances tested. [G. G. S.]

6. Martin points out that the Lane kink of the ileum has its location in the last six inches of the ileum before its attachment to the cecum. It occurs at this point because of the comparatively fixed condition of this part of the gut, due to its short mesentery. The actual cause of the bend in the intestine and the adhesions complicating it and the change in its mesentery are due to traumatism as a result of the prolapsed cecum dragging upon it, or the pulling of the rest of the intestines upon it. Thus a bending of the ileum in one or more places, obstructing its lumen, is produced. The symptoms are acute colicky pains or a dull, steady pain due to chronic stasis subject to exaggeration when the intestines are overloaded. The location of the pain is generally one inch below and to the right of the umbilicus. There are occasional attacks of acute or subacute obstruction, relieved by recumbent position and dieting, anorexia, indigestion, with gas formation and general toxemia due to intestinal stasis. The treatment is laparotomy, separation of adhesions, straightening the intestine, replacement of organs with interposition of a pad of omentum as a bolster and the constant use of abdominal supporters and pads supplemented by repeated assumption of the Trendelenberg position with massage in this position.

7. Lespinasse and Fisher quote Brewer in speaking of the etiology of melena neonatorum as follows: "The latest accepted theories of melena neonatorum point not to ulceration or to gross lesions, but to the capillary blood vessels as the source of the bleeding, and the clinical picture of these cases is undoubtedly very like that of an infection as the etiological factor. But the course and the remarkable cure of the case reported here would seem to disprove both the infectious theory of its origin and the blood vessel explanation of the diapedesis of red cells and undisturbed osmosis resulting in the capillary hemorrhage. At the time of the operation the baby was in a dying state; immediately after, the baby was in perfect health. There was no period of convalescence. Such a sudden change in condition could not be due to a structural generation in the capillary vessels nor to a sudden overcoming of an infection. The only possible explanation of so rapid a change must be found in a chemical condition of the blood. And the final conclusion as to the nature of the disease is a congenital malformation of the blood of unknown chemical nature. The solution of the problem of its etiology is to be found in a chemical study of the process of osmosis in the capillary vessels and of the chemistry of the coagulation of the blood."

The authors consider the father the best donor. In six cases transfused an immediate cessation of hemorrhage has been effected in all and immediate noticeable increase in bodily vigor. They claim direct transfusion of blood as the ideal treatment for melena neonatorum as it immediately overcomes hemorrhage, anemia and infection. In

the cases without syphilitic taint it is an absolute specific. It should be performed at the very onset of the symptoms. [E. H. R.]

2. Herts shows that the stippling granules are decidedly different particles from those that are stained by the vital stains in the red blood corpuscles. These vital staining granules appear in large numbers in all anemic conditions. These granules are not a consistent accompaniment of lead poisoning, but point more to blood regeneration. These granules and polychromatophilia are substantially identical. [C. F., Jr.]

9. Runge takes up the various operative measures now in vogue in the treatment of placenta previa, stating the advantages and disadvantages of each method. He reviews the controversy over Cæsarian section as the safest and surest treatment of placenta previa, pointing out the arguments against this measure, namely, that as this treatment must, for the most part, be reserved for hospital use solely, the student should have his attention drawn to a method which will yield good results in the hands of the general practitioner. Packing the vagina should seldom be employed and never in a hospital. The simple rupturing of the membranes yields excellent results in a large proportion of cases. But in complete placenta previa this should not be employed, as it cannot accomplish the results desired and merely increases the danger of severe hemorrhage. In complete placenta previa the Braxton-Hicks version is the operation of choice in spite of the high infant mortality. Runge urges the inflated rubber balloon inside the uterus as the most satisfactory of all methods in dealing with this complication. He describes the technic in detail. [J. L. H.]

3. *Purpura, F. *The Streptotriches and Their Action in Experimental Animals.*
4. *Gambaglio, R. *Fractures of the Carpal Scaphoid.* (Conclusion.)

1. Alessandri reports a case of apparently primary tuberculosis of the myometrium, without lesion of ovaries, tubes, serosa or endometrium. He believes the infection to have been hematogenous, from some old focus clinically unrecognizable. The patient recovered after subtotal hysterectomy. The author collects from the literature ten similar cases, in only one of which, however, was the tuberculous process limited to the uterine musculature.

3. From an elaborate laboratory study of the various streptotriches found in the mouths of animals, Purpura finds that some of these are virulent and produce forms of infectious granuloma. Others have little or no virulence and behave in the tissues merely like a foreign body. The species of streptothrix, he believes, cannot be classified by their color reaction in culture media, but may be classified by their morphologic, cultural and biologic characteristics.

4. In the conclusion of his article on fractures of the carpal scaphoid, the author presents ten cases from his own experience, with admirable x-rays and plates. [R. M. G.]

2. Longo reviews the literature of tetany in children and reports a few cases. Chemical researches, he says, show that in children subject to spasms the blood is deficient in calcium and the brain contains less of this element than normal. The minimum retention of calcium is found during the height of an attack, and a gradual increase in calcium content accompanies the disappearance of alarming symptoms. Electrical irritability is less in dogs fed on food rich in calcium than in those receiving food poor in calcium. Dogs given a prophylactic dose of calcium salts withstand larger doses of convulsive poisons than dogs not so protected. [L. D. C.]

## Obituary.

### SIGMUND LUSTGARTEN, M.D.

Dr. Sigmund Lustgarten, a well-known New York dermatologist, died on Jan. 22, at the age of fifty-three years. He was a native of Vienna, and was graduated from the university of that city in 1881. He was for many years attending dermatologist to the Mount Sinai Hospital and consulting dermatologist to the Montefiore Home and Hospital for Chronic Invalids, and at a special meeting of the Board of Directors of Mount Sinai Hospital held in his memory resolu-

tions were adopted in which it was declared that "in the death of Dr. Lustgarten the hospital has lost one of the most efficient and conscientious members of its staff, the community an earnest and sincere friend of humanity, and science a pre-eminent leader, who devoted his great talent and energy not only to the alleviation of the sufferings of the afflicted, but also to the deep study of scientific improvement in his special field of labor."

## Correspondence.

### PARIS LETTER.

THE LATEST TREATMENT FOR TUBERCULOSIS. DECLINING BIRTH-RATE IN FRANCE.

[*From Our Special Correspondent.*]

PARIS, Jan. 17, 1911.

*Mr. Editor:* Our friend Doyen continues on his interesting career. Not content to rest on his laurels after announcing the cure of cancer and the disappearance of the entire class of infectious disorders, he has recently concentrated on the tuberculosis question, and various communications to the daily papers, in accordance with his usual custom, have attracted public attention, always on the watch for anything new in this line, to his efforts in that direction.

The basis of his treatment of tuberculosis is one of the tuberculins, helped out by the use of his mycolysine. He has been at this now for several months, has opened one, if not several, special clinics for the purpose, and has awakened quite a following among provincial practitioners. Only recently an entire page in small print of the *Matin* was given up to certificates from a great many quite unknown physicians as to the satisfactory results they had obtained in treating tuberculosis by this method, and in this connection an incident occurred showing what a very cool operator this surgeon is. These testimonials were his, and it is hard to believe that they were published without his knowledge, especially as this page was in reality nothing but a big advertisement for his mycolysine; yet a short time after its appearance he wrote a letter to the *Matin* saying blandly that he had been out of town, had seen their page of testimonials, and wished to congratulate them on the excellent thing they had done in helping on this good work! It is difficult to imagine a keener sense of the humorous than he must have, — or shall we perhaps better put it, a more accurate estimate of the profundity of *la bêtise humaine*.

I saw a bottle of mycolysine the other day. At the top of the label stands: "Institut du Dr. Doyen"; then a statement to the effect that the preparation cures the greater number of infectious disorders; below that, a nice picture of a microscopical preparation in which leucocytes are gorging themselves with various and sundry germs; and at the bottom the name of the chemist by whom the preparation is prepared. It would be interesting to know what would be Doyen's fate if he lived in a country where, as in England, for instance, there is a medical council that looks after the deontology of the profession!

I also tasted the stuff, — just to see, — and found it pretty unpleasant; it had quite an original flavor, which for some reason or other recalled the dissecting-room. I'm rather glad *I* do not have to take tablespoon doses several times a day! It can also be administered hypodermically. My sole experience with this method was that of a lady with whom an injection had been made in the gluteal region by an up-to-date practitioner down at the seacoast somewhere last fall; the injection had given rise to pain, a big lump and some redness, and for a while I was afraid the patient was in for a large abscess of the hip; but in the end the whole affair subsided with no worse results than the suffering and loss of time.

The occasion of my coming across the bottle of mycolysine was this: A lady here, who is studying singing under Jean de Reszke, the celebrated tenor, turned up one day at her lesson with the beginning of a cold, whereupon Jean advised her to get some mycolysine and she would be cured at once! This she did, but as the cold developed into quite a little attack of influenza, she became alarmed and sent for me. I also found it at another patient's house, the other day, under similar circumstances, influenza, but prescribed this time by a lady friend. These instances throw light on two points: The value of medical advertising in the daily press, and the boundless stupidity of women in everything medical; this latter is something I never can grow reconciled to, in spite of gray hairs and a quarter of a century's medical experience. And it seems to me as though the better the class of woman and the more wide-awake her mind, the bigger fool she is in medicine.

But I am afraid that since on several occasions I have had to cite the *Matin* in connection with Doyen and his doings, some of your readers may think that this paper occupies itself almost exclusively with this subject! Such is far from being the case. The *Matin* is a wide-awake and well-informed daily, and, considering its small size and generally poor appearance in comparison with the papers English-speaking people are used to, manages to cover a pretty wide field.

It came out, for instance, recently with a leading article by Lacassagne, a Lyons professor, concerning race suicide in France that must have been a disagreeable surprise to many a Frenchman. It has, of course, long been common talk that the population of France has ceased to increase; in fact, for the past few years, the deaths have been slightly in excess of the births; as the case now stands, the German empire adds close on to one million to its population each year, whereas its next-door neighbor to the south is in round figures altogether stationary. This is certainly a very curious state of affairs, for there is no lack of prosperity in this country.

There are naturally various ways in which the natality of a country may be forced down; in France, for instance, it is said to have decreased during the last century from 32% to 20%, or more than one third. Thus, there may be disinclination to marriage on the part of the men, on account of the burdens and responsibilities it imposes. There may be deliberate prevention of conception among married couples during the childbearing age. And there may be wilful interruption of conception once established.

That all three of these causes take an important part in the present situation in France does not admit of any doubt, but what is of particular interest is the pitch to which abortion has now risen, if we are to believe Lacassagne's figures, which are, after all, only estimates on the part of himself and various colleagues interested in the same branch. For whereas that men should not want to marry, or that married couples should so arrange matters that the wife does not become pregnant, concerns no one but the immediate parties and their views on social economy, the wilful interruption of pregnancy is considered to concern society at large, and when proved brings the party up for punishment.

Now Lacassagne says, what every practitioner has had occasion to observe, that at least among the inhabitants of the large centers the induction of abortion is looked on among women as a matter of no consequence whatever; they do not even make a pretence of concealing it, or of being ashamed of it. How many women have said to me, in reply to my refusal to have anything to do with them: "Why, doctor, if I were at home my family physician would attend to it at once; he has done it —— times for me before!"

But I must admit that even though we are all more or less aware of this state of things, I, personally, was not prepared for such figures as Lacassagne cites in his article. He says that both for Paris and Lyons the yearly abortions performed *exceed the number of children born;* and that if the entire country is considered, with its 700,000 births per annum, the abortions reach fully 450,000 or 500,000. Doléris has written that in the Maternities fully one quarter of the beds are occupied by women on whom abortion has been performed, and that in a single year in Paris between four and five thousand such cases are cared for in the hospitals. Naturally it is only the bad cases, the ones that go wrong, with infection, that reach the wards; and if this figure be exact it is not difficult to

believe that, as Lacassagne says, there must be fully 70,000 abortions performed in Paris *per annum*.

In connection with the figure 700,000, the total annual baby output of France, it is interesting to note that the Germans manage to get an actual annual increase of population (deaths deducted) considerably greater than France's entire annual birth figure!

This question of natality is naturally an important one, and one on which there is much to say from various points of view. I once heard Charcot, for instance, remark to his audience, in this connection: "Who knows? It is not impossible that France's disinclination to increase her population may at some future day be laid *to her credit*. In this way, at least, we do not grow overcrowded, and are not obliged to go warring around with other races to make room for a surplus that cannot find place at home!" The theme that it is the *duty* of married people to have children for the benefit of the society to which they belong, and that in not doing so they are *defrauding* the state of a right, has always seemed to me to have one very weak point. It may be all very nice in theory that a couple should have children, be attached to them and spend endless time and money on bringing them up, — to in the end have a war brought on by some ruthless statesmen and the children disappear like so may rabbits, killed in some engagement. But all contracts have two sides, and it is the state's side that seems to me to be altogether absent in this case, or virtually so. Does the state afford any guarantee whatever that if a couple have children, bring them up in ordinary comfort, and the head of the family dies, leaving the others absolutely unprovided for, it will continue to minister to their wants on the same scale? Not at all. All it undertakes, and that very grudgingly and in the least liberal manner possible, is to see that they do not actually perish from want. The whole contract is so manifestly unfair that it is not possible not to see that there is a great deal to be said for families living on moderate salaries, with nothing whatever back of them in the way of resources, limiting their offspring to what they consider they have a fair chance of being able to bring up decently. It seems to me that such people can very well reason to themselves: "When I am convinced that the state will think of me when I am in trouble, in the same manner that it forces me by taxes and military service to think of its needs, then I will see about the large family; in the meanwhile I shall think of myself and my wife." Again, is it any service to either state or your children to procreate a large family, when you know that you have not the means either to educate them or to start them in some path in life? I cannot think so.

In this French birth-rate question I have many times been led to reflect on the illustration afforded by the house in which I live. In Paris, as you know, the immense majority of the population lives in what is known as flats; thus my house is composed of two parts, a front and a back, separated by a court, and has twenty flats, containing about as many families. I have lived in this house for the past ten years. Now how many babies do you suppose this little agglomeration has turned out during these ten years? As near as I can recollect, *three*. So you see that at least in this house we are lamentably weak as regards our duties toward the state! Where we come out strong is in the dog line. This house is a regular kennel. From the proprietor down, every family keeps a dog, when it hasn't two! I wonder the police hasn't taken the matter up. And the proprietor, who is a bit of a joker in his way, has a printed clause in all his tenants' leases to the effect that they shall not be permitted to keep noisy pets that can in any way annoy the other tenants. Now all our dogs bark at each other out of the windows more or less the livelong day, especially in good weather when everything is left open, and make at times a gruesome din. But, you see, no one can complain; the retort would be too easy! "*S.*"

## CHARLES II — A THERAPEUTIC NIHILIST.

BOSTON, Jan. 27, 1911.

*Mr. Editor:* Charles II of England was in early life a witness to the miseries of his father, Charles I, and the troubles of the period. When only twelve years of age, he viewed the battle of Edgehill from an eminence. The king's bodyguard having requested permission to charge in front of the line, the prince and his brother, the Duke of York, were left almost unattended. During the action they were entrusted to Dr. William Harvey, and the latter, having withdrawn under the cover of a hedge, is said by Aubrey to have taken a book from his pocket and, quite heedless of the din of battle and the enormous stake which was being played close by, to have speedily become completely lost in meditation. A cannon-ball, however, grazing the earth beside them, the great physician shifted his position.

It would also appear that the young prince was averse to the taking of physic, as was the practice of the time, as is evident from the two following letters. The queen's note is a curiosity, as being one of the few letters of Henrietta in the English tongue which have been handed down to us. It is written entirely in her own hand. Charles was at the time between seven and eight years of age:

"*Charles,* — I am sore that I must begin my first letter with chiding you, because I hear that you will not take physic. I hope it was only for this day, and that to-morrow you will do it, for if you will not I must come to you and make you take it, for it is for your health. I have given order to my Lord Newcastle to send me word to-night whether you will or not; therefore, I hope you will not give me the pains to go; and so I rest,

"Your affectionate mother,

"HENRIETTE MARIE R.

"To my dear Son the Prince."

It can scarcely be doubted but that Charles had his mother's note in mind when he addressed, about the same period, the following note to his governor, the Earl of Newcastle. It is written in the child's own hand, with lines ruled in pencil above and below.

"*My Lord,* — I would not have you take too much physic, for it doth always make me worse, and I think it will do the like with you. I ride every day, and am ready to follow any other directions from you. Make haste to return to him that loves you,

"CHARLES P.

"To my Lord of Newcastle."

Very truly yours,

CHARLES G. CUMSTON.

## ELEVATORS AT ELEVATED AND SUBWAY STATIONS.

*Mr. Editor:* With several elevated and subway railways in operation or in course of construction, and new ones proposed, the matter of ascent and descent at stations furnishes a problem that appeals to physicians. If the surface lines could still be used it would not so much matter, but it is already impossible to reach the business district from some quarters by surface lines, and the same may become true of other quarters. Thus people who are obliged to earn their livings are compelled to make the ascent at stations.

This is not an unimportant matter. I recall a lady who always leaves Boylston Street cars at the subway entrance and walks rather than climb the stairs at Park Street; another who on going to her brother's office in Bromfield Street always, while she could, approached it by Tremont Street and left it by Washington, in order to avoid the slight ascent in Bromfield Street; also a gentleman with an office in Pemberton Square who regularly approached it by entering the store of Houghton & Dutton, going up in the elevator and leaving by the second story into the higher level of Pemberton Square in order to avoid the ascent in the street; all these people had bad hearts. The interesting thing is that none of them had received medical advice on the subject, but had found for themselves that the ascent did them harm. Doubtless examples will occur to any practicing physician. I have notes of several children with bad hearts who seemed well enough until their classes at school were changed from a lower to an upper room, but in whom the final break quickly followed the change.

In certain cases an attempt to supply these needs has been made by the introduction of a moving staircase.

Any one in good health can use it, but just the people who need it most cannot. It is evidently impracticable for the infirm, the lame, or for women carrying babies. A real elevator is needed.

This will probably cost more money in its operation than the moving staircase. Whether this money is to be found by the railway company, and if found, whether it is to be replaced by not extending the five-cent fare further into the country, or whether a separate fare is to be charged in the elevator, and if so, what it is to be, are all practical questions that do not concern us as physicians. What does concern us is that an elevator is needed at many stations that cannot be reached by the surface. This is a matter on which we should have an opinion and be ready to express it.

Yours truly,
EDWARD M. BUCKINGHAM, M.D.

## LECTURES OF FORMER PROFESSORS OF THEORY AND PRACTICE OF PHYSIC AT HARVARD.

JAN. 25, 1911.

*Mr. Editor:* Developments in medicine are well mirrored in lectures given to medical students at varying periods. In order to preserve such documents for future medical historians, I have sought to collect volumes of students' notes on the lectures at Harvard given by the professors of theory and practice of physic. I am desirous of completing this series by obtaining notes of lectures by Drs. Benjamin Waterhouse (1782–1812), George C. Shattuck (1859–1873) and Francis Minot (1873–1890). These volumes will be presented to the Harvard Medical School and preserved in its library. If any one can supply such volumes, I shall be glad to correspond with him with a view to obtaining the volumes for this purpose by donation or purchase.

Very truly yours,
HENRY A. CHRISTIAN, M.D.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JAN. 21, 1911.

## SOCIETY NOTICES.

THE AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION. — The date of the meeting of the American Gastro-Enterological Association has been changed. The meeting will take place April 19 and 20, 1911, at Philadelphia.

CHARLES O. AARON, M.D., *Secretary.*

AMERICAN LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL SOCIETY. — A meeting of the Eastern Section of the American Laryngological, Rhinological and Otological Society will be held in Boston on Saturday of this week, Feb. 4. The morning session will be at the Massachusetts General Hospital; the afternoon session at the Harvard Medical School.

## RECENT DEATHS.

DR. JOSEPH F. GRAINGER, who died of pulmonary hemorrhage last week at Cambridge, Mass., was born in Cambridge in 1882. He received the degree of M.D. from Tufts Medical School in 1906, and since that time had been practising his profession in Cambridge.

DR. FRANK GUY SHERWOOD, who died of pneumonia last week at Albion, N. Y., was born in Millville, N. Y., in 1850. After graduating from the University of Michigan, he received his medical degree from Buffalo University. He had practised medicine at Rush, N. Y., at Superior, Wis., and at Albion. He is survived by his widow, one daughter, and two sons.

DR. GEORGE F. WILBER, of Nashua, N. H., died in that city, on Jan. 21. He graduated from the Long Island Medical School in 1864.

DR. JOHN EVANS, an American dentist who had practised for many years in Paris, died there on Jan. 29.

DR. HENRY C. NEER, of Park Ridge, Bergen County, N. J., died in the Hackensack Hospital, on Jan. 27, while undergoing an operation for cancer. He was a native of Schoharie County, New York, and seventy-two years of age. He was graduated from the Berkshire Medical College in 1860, and had practised in Bergen County for forty-five years. One of his sons is Dr. Charles Neer, a physician of Baltimore.

DR. ARTHUR W. BLAIR, of Dorchester, Mass., died suddenly Jan. 18, 1911, at Duxbury, Mass., while attending to his professional duties. Dr. Blair was born at Plymouth, N. H., May 22, 1848; a graduate of Dartmouth College in 1872, receiving the degree of A.M., 1875, from Dartmouth College, and the degree of M.D. from the University of Vermont, 1881. He had been in practice in Dorchester for twenty-five years. He was a member of The Massachusetts Medical Society, New Hampshire Medical Society, American Medical Association and the Dorchester Medical Society. He was the medical director for the Commercial Travellers' Eastern Accident Association and medical examiner for other accident companies. He was a man who was highly esteemed by his associates and in the community.

## Original Articles.

### SPOROTRICHOSIS IN MAN AND IN THE HORSE.

BY RICHARD L. SUTTON, M.D., KANSAS CITY, MO.

DURING the past four years numerous instances of sporotrichal infection have been reported in France. The first case of the disease in man was recorded by Schenck [1] in 1898. Since that time more or less typical examples of the affection have been described by Brayton,[2] Hektoen and Perkins,[3] Burlew,[4] Trimble and Shaw,[5] Stelwagon,[6] Pusey,[7] Hyde and Davis,[8] who include Zuraski's case, and myself [9] in America; while in France, De Beurmann and Gougerot,[10] Monier-Vinard,[11] Dor,[12] Widal and Weill,[13] and a score of others have studied the disease.

The pathology of the lesions and the cultural characteristics of the organism were so thoroughly investigated by Schenck and Smith and by Hektoen that these fields were practically exhausted. De Beurmann and his colleagues deserve much credit for the care with which they have carried out their experimental studies on animals; in fact, so exhaustively has this been done that later investigators in other countries have only duplicated the work of these pioneers. Gougerout [14] insists on certain morphological and cultural differences between the fungus as encountered in France and in America, but Lutz and Splendore [15] and Page, Frothingham and Page [16] claim that a distinction does not exist and that the sporotrichal organism is one and the same in the two countries. I have studied the fungus as isolated from four cases of the disease in man, and the differences noted when various culture media are employed are to me sufficient evidence that the conclusions of Gougerout, Matruchot [17] and other French writers are not well founded and cannot be accepted. The original name (Sporotrichum schenckii) suggested for the organism by Smith should be retained, and needless confusion avoided.

At present, in the United States, we are interested in the affection more from a practical than from a theoretical viewpoint. The disease is undoubtedly a fairly prevalent one, particularly in the middle west, and in the majority of instances the true nature of the infecting agent is not recognized because the medical attendant is not familiar with its clinical manifestations. Usually an incorrect diagnosis of syphilis, tuberculosis or coccic cellulitis is made. When the characteristic symptomatology of the disorder is borne in mind, this mistake is not liable to occur. As I have pointed out in a previous communication, a traumatic lesion of the arm, forearm or leg which proves resistant to ordinary surgical treatment, and is accompanied by the development of one or more sharply circumscribed, painless, cutaneous or subcutaneous abscesses along the course of the limb, should always arouse suspicion, especially if the inflammatory manifestations typical of a streptococcic cellulitis are absent. It is extremely difficult to recover the causative agent directly from the lesions, although Page, Frothingham and Page found fragments of the organism in the broken-down tissue cells surrounding an abscess cavity. A much easier and simpler method is to aspirate a few drops of the tenacious, chocolate-colored fluid, and cultivate the fungus on artificial media. The organism is a strict aerobe, and, in consequence, fluid and débris obtained from an open lesion generally contain more and healthier fungi, but material secured from these locations is frequently contaminated with other molds and bacteria. Abundant growths can easily be secured on practically all ordinary culture media, particularly on those which are slightly acid.

Recently, a number of instances of sporotrichal infection in horses has been studied (Page, Frothingham and Page; Hyde and Davis). The first-named authors emphasize the differential points existing between this disease and epizootic lymphangitis (a disorder due to infection with the saccharomyces farcinimosis of Tokishiga [18]).

In the case reported by Hyde and Davis the affection was probably contracted from a horse which presented clinical evidence of mycotic lymphangitis.

Recently I have had under my care an instance of this disease in man in which infection very probably occurred through a similar source.

Patient, J. C., a man aged forty-four, farmer, seen in consultation with Dr. S. G. Ashley, of Earlton, Kan. The cutaneous history of the family is negative. The patient is a native of Ohio, and a resident of

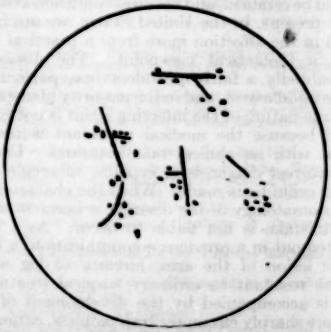
FIG. 1.

Neosho County, Kansas. His general health has always been excellent.

In November, 1909, one of his horses was accidentally

cut with barbed wire on the left shoulder. The wound healed very slowly, although it did not appear to pain the animal, and there were no signs of the presence of a severe or widespread inflammatory process. About six weeks after the injury was received, several hard lumps, varying in size from a large bean to a hickory-nut, appeared beneath or in the skin on the left side of the animal's neck. These nodules were irregularly arranged and apparently painless, and remained hard and firm to the touch for about a fortnight. Then they

FIG. 2.



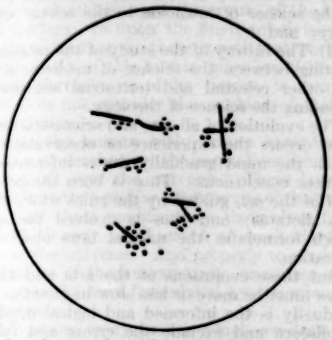
gradually became soft and compressible. At one point the overlying skin broke down, and small amounts of thick, tenacious, brownish pus exuded. The discharge continued for several weeks, although spirits of turpentine, pure carbolic acid and other antiseptics were freely employed. The other abscesses did not rupture, but finally disappeared, although the original wound on the shoulder and the ulcer on the neck were not completely healed until June, 1910. No internal treatment was used, and no bacteriologic cultures were made. None of the other animals were known to contract the disease.

*Present illness.* — In May, 1910, while repairing a manger in the barn by means of a piece of baling wire, the patient sustained a punctured wound of the right wrist. The injury was slight, and at the time but little attention was paid to it. One week later the lesion had considerably increased in size, and a firm, flat-topped, painless, reddish papule marked the site of the wound. The growth continued to increase in size until it was 4 or 5 cm. in diameter, and 1 or 2 cm. in height. The central portion of the lesion was slightly depressed, and a small amount of blood and pus could be squeezed out. The family physician was then consulted, and he advised free incision and drainage. Deep, transverse cuts were made, but very little pus escaped. The part was then cauterized with pure carbolic acid, and wet bichloride packs applied. Despite this energetic treatment, however, the lesion continued to enlarge. At this time, small, subcutaneous nodules began to appear on the flexor surface of the forearm and upper arm, and, within a period of six weeks, ten of these small, tumorlike masses were present. They varied in size from a butter bean to a large Brazil nut, and were painless and exhibited no signs of acute inflammation. There was no cording of the lymphatics, or enlargement of the epitrochlear or axillary glands, and no elevation of temperature. The nodules broke down in the course of two or three weeks, and fluctuated to the touch. Two of the abscesses were incised the latter part of July, and considerable amounts of brownish, syrupy pus removed. The wounds healed very slowly, and one of them was still present in November, over three months later. The largest abscess was located at a point 15 cm. below the axilla, and was opened and drained on Sept. 16, but did not heal.

*Physical examination.* — The patient was a large, well-built man, six feet in height, and weighed 170 lb. A careful general examination failed to reveal any abnormal condition of the internal organs. The hemaglobin percentage was 88, red cells 4,600,000, and white cells 10,800. A differential count showed the proportion to be: Large mononuclears, 10.6%; transitionals, 2.4%; small mononuclears, 19%; eosinophiles, 14%; and polymorphonuclears, 54%. The mucous membrane of the throat and pharynx was not affected. There were no cutaneous lesions of any kind other than those on the right upper limb.

On the flexor surface of the right wrist was a flat-topped, reddish nodule, 4 cm. in diameter and 1 cm. in height. The epidermis had exfoliated, leaving an irregular fringe which overlapped the base of the elevation. The central portion of the mass was scarred and ulcerated, and pus could be forced up between the points of granulation tissue, very much as in a typical blastomycetic lesion. Manipulation gave rise to no pain, and even the use of a probe caused but slight discomfort.

Between the point of the original wound and the fold of the elbow was a chain of eight lesions, six of which had healed, leaving depressed cicatrices surrounded by pigment. The two remaining foci were still open, and pus exuded when pressure was applied. Only a small scar marked the site of the first abscess that had de-



Mycelia and spores of Sporothrix schenckii from a seventy-two-hour agar culture (Spencer 1-6, Oc. 8x).

veloped on the upper arm, but about 20 cm. above it was a sinus that opened on the surface and communicated with a subcutaneous cavity 2 cm. or more in diameter. None of the lesions gave rise to either pain

or inconvenience in the use of the limb, although the one at the wrist interfered somewhat with the flexibility of that joint. There was no involvement of the glands at the elbow or at the shoulder. The temperature was normal.

*Bacteriological examination.* — A clinical diagnosis of sporotrichosis was made, and pus from all of the four open lesions used for inoculating agar tubes. Growths developed on all of the slants, but only one pure culture was secured, the uncontaminated material coming from the cavity near the axilla. The organism showed the characteristic mycelia (varying in length from 3 to 5 microns), with large numbers of oval conidia (from 1 to 2 microns in diameter).

Mycelia and spores of sporothrix schenckii from a seventy-two-hour agar culture (Spencer 1-6, Oc. 8z).

*Treatment.* — The usual line of treatment, potassium iodide in increasing dosage, which has proved so satisfactory in combatting the disease in other cases, gave excellent results in this instance. The lesion at the wrist was somewhat resistant, probably because the infection was a mixed one (sporothrix and staphylococcus pyogenes aureus), but it healed promptly under the daily application of gauze packs moistened with 1% liquor cresol compositus.

## THE SPECIAL RELATION OF MODERN MEDICINE TO THE HEALTH OF WOMEN.*

BY AGNES C. VIETOR, M.D., BOSTON, MASS.

WE speak of the science and the art of medicine — *art* being defined as " practical skill guided by rules," and *science* as " that which refers to abstract principles, as distinguished from *art*." And gradually these " abstract principles " have come to take the form of a statement of the natural laws manifested in the particular field studied.

In its beginnings, the art of medicine was like all other arts in that it was based upon empiricism, that is, it was the result of what is called *experience* and the traditions of experience. But nothing is so fallacious as experience.

What we call *experience* is made up of two factors: (1) The real fact or occurrence; and (2) the impression which this fact or occurrence makes upon our minds. And these two factors make up what we call our *experience* on any given subject.

Now, experience stimulates two very important instincts: (1) We attempt to use our experience as a guide for future conduct; and (2) we desire to interchange our experiences with those of our fellow beings.

Attempting to use our experience as a rule of conduct, we do so by drawing inferences, and by deducing conclusions from these inferences.

Describing an experience, we tend to associate with it the inferences and conclusions which our particular mind drew and deduced therefrom. And exchanging this mixture of experiences, inferences and conclusions with another person, this mixture is further modified by the inferences and conclusions to which it gives rise in the mind of the other person, and which are, in turn, received by us.

An every-day example of the difficulties in drawing correct inferences and deducing accurate conclusions is the common experience of " catching cold " after wetting the feet or sitting in a draft or sleeping by an open window. In such case, the facts of the wet feet, and the draft, and the sleeping by the open window, and the subsequent " cold," are all *facts* which can be demonstrated. However, the *inference* that the " cold " is due to wetting the feet or having a draft of air blow across one or sleeping by the open window, and the *conclusion* that " colds " are due to wetting the feet or sitting in a draft of air or sleeping by an open window, are both erroneous. Physiological study shows that the condition of ill-health which is called " catching cold " may be determined by a too rapid local or general loss of heat from the body; that the rapidity of this loss of heat is increased by wetting the surface of the body, by rapid movement of the air over the surface of the body or by lowered temperature of this air, such as occurs at night; and that if the surface of the body is kept warm, wetting the feet or any other portion of the body, exposure to drafts or sleeping by an open window, or, indeed, entirely out-of-doors, have no harmful effect whatever.

The incorrect inferences and erroneous conclusions associated with this one group of experiences regarding " catching cold " are responsible for all degrees of indisposition and even serious ill-health in both men and women. But those associated with " wetting the feet " bear particularly heavily on women, since this experience is supposed to

* Address delivered before the Middlesex Women's Club of Lowell, Mass., Nov. 28, 1910.

have a particularly disastrous effect on menstruation.

To this tradition are due a host of indispositions which follow bad hygiene during the menstrual period. Not only is the daily bath omitted — for fear of "wetting the feet!" — but all forms of local and general bathing are omitted or slighted as the result of a similar process of reasoning.

Some women even refrain from washing their faces in water at such times — since they cannot wash their faces without wetting their hands, and, they reason, if it is harmful to wet the feet, may it not also be harmful to wet the hands?

Many women also interrupt their daily hygiene by staying indoors during menstruation if there is rain, or the appearance of rain, or even dampness — again for fear of this terrible experience of "wetting the feet."

And all the indispositions which follow the breaking of normal habits and the living under bad hygienic conditions (due to the influence of these and other fallacious inferences and conclusions), for about one fourth of the menstrual life, are gravely accredited to the normal function of menstruation.

Now, the brains of the men and women who have practiced the art of medicine have followed from the beginning the same laws as have the brains of their fellow men and women.

Hence, the early practice of the art of medicine was similar to the early practice of all the arts, in that it was based upon more or less personal experience, with its personal inferences and conclusions, plus a rapidly accumulating supply of the experiences, inferences and conclusions of other people. And all these experiences, inferences and conclusions have been accompanied by the fallacies inseparable from such mental processes.

Early in human history, the art of medicine became associated with the art of theology, and to a large extent these two arts were not only practiced by the same person, but were so amalgamated that the individuality of the two members of this alloy were confused, and they became for many purposes interchangeable. Thus, theological remedies were prescribed for medical ailments, and medical ailments were viewed as consequences of theological offenses.

This association of the arts of medicine and theology continues to a large extent, even to the present day.

But far back in the history of the race, the human mind began to recognize the relationship of the art of medicine not only to the art of theology, but also to all the celestial and terrestrial arts.

The history of the art of medicine may then be viewed as the history of two great movements:

(1) The history of the study of the relationship of the art of medicine to the art of theology; and

(2) The history of the study of the relationship existing between the art of medicine and all the other celestial and terrestrial arts, not excluding the art of theology.

Side by side with the growth of the *art* of medicine, as thus briefly outlined, has proceeded the growth of the *science* of medicine, *science* being defined as "that which refers to abstract principles" or to the recognition and formulation of the natural laws observed in operation.

And the same two great movements which have dominated the *art* of medicine have also dominated the *science* of medicine. Hence, similarly stated: The history of the science of medicine may be viewed as the history of two great movements —

(1) The history of the study of the relationship of the science of medicine to the science of theology; and

(2) The history of the study of the relationship existing between the science of medicine and all the other celestial and terrestrial sciences, not excluding the science of theology.

The evolution of all arts and sciences is similar. First occurs the experience or observation from which the mind gradually draws inferences and deduces conclusions. Thus is born the practical skill of the *art*, guided by the rules which repetition dictates; and thus is evolved the *science* which formulates the natural laws observed in operation.

But these evolutions of the arts and the sciences must be more or less slow in growth. Only gradually is the informed and logical mind able to discern and exclude the errors and fallacies which accompany all experiences, observations, inferences and deductions. And only by the elimination of these errors and fallacies can we hope to isolate the natural law or laws governing the particular experience or observation.

Owing to the extraordinary difficulties surrounding the subject, the *science* of theology has scarcely taken definition in the human mind, and the existence of natural laws governing it is barely beginning to be recognized. Hence, theology has remained largely an *art* — the exercise of a "practical skill guided by rules." And in so far as medicine has been, or is, associated exclusively with theology, it shares the inchoate condition of theology as a science, and remains an art, with all the tendencies to fallacy which are inherent in all arts not corrected by the sifting processes which develop the associated sciences.

On the other hand, the difficulties surrounding the more material celestial and terrestrial arts have proved less insurmountable. Hence, with the passage of the ages, these arts have attained greater perfection, and their associated sciences have more or less steadily reached clearer definition. And in so far as medicine has been associated with these other arts and sciences, it has shared their greater perfection and their increasing clarity of definition.

Indeed, one may say that the distinguishing feature of what is called "modern" medicine is the recognition of such close relation between medicine and these other arts and sciences that the study of medicine has largely become the study of these other arts and sciences manifested within the environment of the human body.

Thus, the study of medicine to-day is largely the study of physics and of chemistry as manifested in and modified by the human body; and the laws of human physiology are at one with the physical and chemical laws at work everywhere in the universe.

For example, the law of gravitation is the same whether this force be exerted upon a portion of the earth's surface; upon a celestial body wandering within the limits of this force; upon the mass of bones and soft tissues constituting the human body; upon the constituent portions of this mass — the support of the head upon the neck, of the arms and shoulders upon the trunk, of the trunk upon the legs; or upon the finest subdivisions of the tissues making up these constituent portions. And no study of this human mass, or of its constituent portions, or of its tissues, is complete which does not consider the working of this law of gravitation.

Again, the human body moves according to the laws of mechanics, the same laws which are at work all over the universe. These laws are modified by the peculiar constituents of the human body, but these modifications themselves follow laws which may be observed at work elsewhere all over the universe. And properly to study the movements of the human body, one must study and apply the laws formulated by the science of mechanics.

And, again, every breath which we draw into our lungs is initiated by the working of universal physical and chemical laws; and the action of the breathed air when it reaches the depths of the lungs is again in accordance with laws which may be demonstrated in any laboratory upon a large variety of materials. And one cannot understand the physiology of respiration without studying the laws formulated by these sciences of physics and chemistry.

So it is with every portion of the structure of the human body, and with every function of every portion of this structure. Everywhere, the action of the general laws of physics and chemistry can be demonstrated with increasing facility, and human functions can be shown proceeding as the result of the operation of these laws.

Indeed, the most profound advance in modern medicine is due to the work of a chemist, Louis Pasteur, and his studies upon the problem of fermentation.

No more striking example of the relation of medicine to the other arts and sciences can be adduced than the statement that this botanical and zoölogical work of a chemist has revolutionized the science and art of medicine.

Largely as a result of this work of Louis Pasteur, modern medicine has found itself closely allied with the arts and sciences of botany and zoölogy. Not only is there a close analogy between the life processes of the human being and those of the whole animal and vegetable kingdoms, but the study of the lower grade of plants and animals is closely related with the modern definition of many of the illnesses which have always devastated mankind.

The study of the molds, of the algæ which fill our small quiet waters, of the mosquitoes and flies which plague the world, has down the ages seemed far removed from the multitudes falling by the way along the pilgrim paths to the world's Meccas; or besieging the temples, the tents of the medicine man or woman, the hut of the witch doctor or the dusky interiors of the traffickers with the so-called supernatural.

Yet it is this study of the molds, and the algæ, and the small insects which is promising to eradicate from the world the plagues which have decimated the peoples and turned the pages of history.

Thanks to our knowledge of the associated sciences of botany and zoölogy, smallpox is entirely in our control, as are malaria and yellow fever. Tuberculosis, typhoid fever, cholera and dysentery will be in our control as soon as we exert the power which we possess to exterminate them. Diphtheria is shorn of its terrors; measles, whooping cough and scarlet fever are coming under control; and those strongholds of the occult, infantile paralysis and cerebrospinal meningitis, are already located and besieged by the allied sciences.

This brief outline of the meaning of "modern" medicine has been necessary to enable us to consider what special relation it has to the health of women.

Perhaps the most prominent characteristic of modern medicine is its attitude towards its problems. It is difficult to describe this attitude briefly, but perhaps it may be described as an attitude of open-mindedness, of desire to learn all the details of the case, of acknowledgement of inability to reach a conclusion till all circumstances have been weighed and considered, and, finally, of a willingness to admit that even after all methods of study have been exhausted, one may find it necessary to confess an inability to solve a particular problem and to admit the necessity of waiting and seeking for further data.

This, the mental attitude developed by the association of medicine with the exact sciences, contrasts strongly with the mental attitude developed by the former association of medicine with theology, and characterized by the assumption of occult powers which conferred omniscience and infallibility.

In no branch of medicine has the former medical attitude been more productive of disastrous results than in that concerning the health of women; and in no branch of medicine is the attitude of the student of the exact sciences more necessary.

Woman has been called the *weak* sex, but a timely remembrance of the weakness of man changes the adjective to the comparative, and we ascend the scale to become a *weaker* sex.

Let us not accept even this label without examination as to what we really are. The study of human history, the study of the related history of the animal series, of which we stand as the

highest evolution, both show that we are the source, the reservoir, the storehouse of the race. As are we, so is the race. And what are we?

We are the Primal Women — as strong, as vigorous, as self-sustaining, as independent — the equal of the primal man — in the sense that the lioness is the equal of the lion, the tigress of the tiger, the mare of the horse, the female eagle of the male eagle, the female fishes of the male fishes, the female of all the animal series of the corresponding males; as strong and as healthy in our individual lives as the men — and, in addition, bearing and nursing our children, carrying on the line of the race.

We are the Primitive Women — co-operating with the primitive men in forming families and communities. We are as strong and as vigorous as our men. They go forth in the early morning to hunt, to procure the flesh food and covering necessary for our common survival. We remain behind to carry on the community life; pursuing the industries we have developed; rearing our own children; helping to rear all the children; caring for the sick and the old whom we no longer abandon, but cherish.

When our men are returning from the chase, the strongest of us go to meet them and carry home upon our broad, strong backs the animals they have killed. Then, as the men repose, it is we who prepare the food; and when the food is eaten, it is we who clear away the remnants and arrange the more durable parts of the food animals for further preparation the next day — and, in addition, bearing and nursing our children, carrying on the line of the race.

We are the Women of the Older World, — Asiatic, African, European — Egyptian, Assyrian, Babylonian, Greek, Roman, Hebrew, Goth, Hun, Gaul, Angle, Saxon and Celt are we, — strong and vigorous as the men. We helped upbuild our various civilizations; we shared in all their beginnings, their attainments, their triumphs, their defeats, their wars, their plagues.

We shared with them their conquests; with them, we were conquered; but with them, we survived; we made new beginnings; founded new communities; and always and everywhere, we continued to work along the lines of our foremothers, and in extensions of these lines, as our individualities found growth and sought expression in such extensions — and, in addition, through all vicissitudes, we bore and nursed our children, carrying on the line of the race.

We are the Pioneer Women of the New World, as strong and as vigorous as our men; doing our share of the conquest of the new world; carrying on the household and neighborhood industries; keeping the family and community life coherent; caring for all the children, the sick and the old; in the absence of our men, tilling the fields and carrying the gun; and doing anything else left undone by the men — and, in addition, bearing and nursing our children, carrying on the line of the race.

We are the Women of To-day. And to-day the cry goes up that we are weak, and that the race is failing because of our weakness.

Let us examine this accusation. Biology teaches us that the two determining factors in all living matter are heredity and environment. We have just outlined our heredity. There is no weakness there. — Always there have been some weak women, but the trend of the tide is taken from its broad current, not from the back waters that slip sideways into the salt pools and marshes.

Our heritage is one of strength, of vigor, of attainment and of reproduction, of hard, strenuous, individual work; and of the incidental bearing, nursing and rearing of strong, vigorous sons and daughters, fitted to inherit the earth.

Since no fault lies in our heredity, let us examine our environment.

Again scrutinizing the pages of history for our earliest information, we see that with the giving up of the primal freedom of the individual, and the assumption of the co-operative family and community life, a great change occurred in our environment — a change from the irresponsibility of the free, unrelated life to the life where new responsibilities waited on every relation, every action and, indeed, almost every thought.

As these relations developed, the natural laws to which we referred in the beginning of this paper were called into operation, and the minds of the individuals making up the communities were impressed by their observations and experiences in this direction. Following these impressions, inferences were drawn and conclusions deduced. And these conclusions, with their inevitable errors and fallacies, led to the formulation of community rules or laws, no less binding because at first unwritten.

All down the pages of history we see these unwritten laws — founded on false as well as true impressions, choked with fallacies, incorrect inferences and erroneous deductions, fettering and crippling the bodies (as well as the minds) of both men and women.

Heavily as these false laws have borne on men, they have borne still more heavily on women, the woman being the more complex creature.

Such centuries-old false environment can be corrected only by patient inquiry, by single-minded desire for the basic facts and by constant guarding against rash inference or unjustified deduction.

This is the task of the exact sciences, and especially of modern medicine, which is now determined to make itself worthy of a place among the exact sciences, and to govern its art accordingly.

In this task, some of the facts with which we find ourselves confronted are an increasing invalidism among women; an almost matter-of-course individual expectation of menstrual stress; a frequent failure of pregnancy; a decrease in the number of children we bear; a decrease in the number of children we are able to nurse; a large number of childbirths which bear on us heavily at the time, so that we require artificial assist-

ance, and from which we emerge grievously wounded, so that we need surgical repair; a frequent subsequent sterility; a large mortality in early infancy; a frequent individual history of complications and pathological developments at the menopause, the cessation of the menstrual function.

These are grave conditions — grave for us as individuals and grave for the race of which we are the storehouse.

(The causes of the complications of the menopause still remain largely in obscurity and hence cannot profitably be dwelt on here. It is, however, of vital importance to call your attention to one well-established fact, i. e., that the great complication of this period, as well as of the entire menstrual period, is *malignant disease* (*cancer*); and that the only chance for controlling malignant disease lies in its early recognition. Hence, every departure from the normal — every smallest lump or spot in or on the breast, every irregular discharge or flow — should be viewed with suspicion until malignant disease can be excluded. And this can be done only by early medical or surgical examination.)

But there are other facts. What does it mean that being born with as sturdy and well-formed bodies as boys, by the time childhood is well advanced, 70–90% of girls have developed *curvatures of the spine*, as compared with 10–30% among boys?

What does it mean that 80–90% of girls develop *weak foot*, the first stage of *flat foot*, compared with 10–20% of boys?

What does it mean that *incompetence of the abdomen* and *dislocation of the internal organs* (splanchnoptosia) predominate in women?

What does it mean that *gall-bladder disease*, with or without stones, occurs in 75–80% of women as compared with 20–25% in men? And that in 90% of these women, its development bears a definite relation to pregnancy or childbirth?

What does it mean that *hysteria* has been so predominantly a disease of women and girls that its very name has been derived from the womb?

What does it mean that *hyperthyroidism* occurs in 80–90% of women as compared with 10–20% in men?

Studying these two groups of facts, one common characteristic pervades them — the characteristic of stress, with struggling for compensation.

Taking the second group by itself, we note that all the structural and functional weaknesses there enumerated are common to both men and women, boys and girls; but that more women and girls succumb to the stress than do men and boys.

Is the explanation of this result that women and girls are weaker than men and boys; or that men and boys have greater compensating advantages?

What are the further facts, so far as we know them? They are, briefly that the modern treatment of *curvatures of the spine;* of *abdominal incompetence;* of *dislocation of the internal organs* (splanchnoptosia); of *falling of the arch of the foot* — is directed towards the upbuilding of the muscles that support and control the various portions of the body named, and towards so changing the clothing and shoes as to permit free use of these supporting and controlling muscles.

Is, then, the greater weakness of women's backs, loins, abdominal walls and feet due to the unwritten laws which limit muscular activity for girls and women, while encouraging it for boys and men?

Is it due, also, to the hampering and deforming standards of dress and shoes prescribed by these unwritten laws for women and girls, but modified for men and boys?

As to *gall-bladder disease*, with or without gallstones, modern medicine is finding evidence that this is determined by bacterial infection. Is its more frequent occurrence in women related to the more frequent occurrence of the structural weaknesses already described — weaknesses making for diminished resistance and so making for greater ease of infection? Whatever the determining cause, gall-bladder disease is now recognized as a frequent basis for much obscure pain and so-called "indigestion" or "dyspepsia" which weaken and incapacitate many women as well as some men.

As to *hysteria*, modern medicine is demonstrating that this disease is absurdly misnamed, since its seat is in the brain, not in the uterus. Is its more frequent occurrence in women due to similar fallacies in the unwritten laws that have determined the training of the brain in women, and hampered the development of the higher controlling faculties of this organ? Whatever the reason, this weakness of the higher centers is responsible for much of the weakness and loss of efficiency in women and girls as well as in men and boys.

As to *hyperthyroidism*, this obscure form of auto-intoxication, due to over-activity of the thyroid gland, is being increasingly recognized as the cause of many symptoms of weakness, nervousness, inefficiency and sometimes death in many women as well as in some men. There is no question but that the obscure and intermittent forms of this disease are the cause of much so-called "hysteria" and "neurasthenia."

Considering now the group of menstrual and childbearing weaknesses enumerated, modern medicine has shown that *venereal infection* is the great source of childbearing disease and weakness; that it is responsible for much sterility; that it causes the largest number of the failures of pregnancy; that it causes large infant mortality, both before and after birth; that it is responsible for the majority of the serious pelvic operations which women are obliged to undergo; that one form of it produces one-child sterility; and that it is the cause of much chronic invalidism in women who survive its acute onslaught.

So it appears that regarding this question of the weakness of the Women of To-day, modern

medicine finds two great causes at work in their environment:

(1) (*a*) Structural defects in their framework; leading to weakness and inefficiency, to the development of internal weaknesses and dislocations and to a lowering of resistance to infection.

(*b*) Defects in their mental training, leading to lack of balance in mental equilibrium and control, this in turn favoring the development of physical weakness and inefficiency.

(2) Infection, especially venereal infection.

As to the remedy. A curious unity runs through the development of all these sources of weakness, inefficiency, disease and death. They can all be traced to the application of unwritten laws founded on incorrect impressions, false inferences and erroneous conclusions. The remedy is, therefore, largely a matter of education. This can be only outlined here.

Taking first the matter of venereal infection. Men must be taught the necessity of avoiding infection; women must be taught the necessity of protecting themselves from infection; boys and girls must be taught sex hygiene, to the end of eliminating the fountain-head of infection.

Taking then the matter of development of the body and the mind, we must all realize that it is wrong to educate the growing girl-child's body and mind according to some fancied "feminine" standard; that the ground plan of the body and mind of both the girl and the boy are *human* in model; that the existence of common muscles and common mental faculties, and their similar response to common stimuli and laws, are indications for common lines of exercise and cultivation; that sex characteristics are secondary and subsidiary to generic characteristics; that sex specialization normally follows upon the establishment of generic growth; and that the individual must be conserved if the race is to be preserved.

Wherever these natural laws are allowed free play and the muscles are permitted to grow and develop in their natural balance, one sees a woman strong and vigorous; with head held in poise on an erect spine; with breadth and depth of chest sufficient to hold large and vigorous heart and lungs; with strong, able arms, terminating in large, efficient hands; with broad waist and expanded lower ribs, making room for the great organs of digestion and internal chemistry; with broad, strong loins and straight, strong abdominal walls, able to support the abdominal organs and the superincumbent weight; with relatively small hips and thighs, well-modeled by muscles and unburdened by superflous fat; and with large, efficient feet, with broad forefeet, long, straight supple toes, firm arches and straight ankles, which sustain and move the whole body, keeping it always in equilibrium.*

* Contrast this figure with the degenerated, so-called "feminine" figure; with the head drooping forward or sideways on a thin, weak neck; the narrow, sloping shoulders; the narrow, flattened chest; the laterally or antero-posteriorly curved spine; the shrunken, retracted lower ribs and waist; the narrow, weak back and loins; the sagging abdomen (revealing displaced or "floating" internal organs); the inefficient thighs, large with impeding fat, but weak in muscle; the bulging inner ankles, with falling arches; the small, weak, splayed feet, with narrow stunted forefeet and distorted toes — all evidences of structural stress, with failing compensation.

Can it be doubted that if this woman escape infection, she can to-day bear and nurse her children as incidentally to a vigorous individual life as did her foremothers?

More and more, the researches of modern medicine show that this is the woman who is struggling to find expression in the Women of To-day.

[It is interesting to observe the resemblance of the synthetic woman outlined above to the Greek statue of the Venus de Milo. Since this Venus has been accepted by the instinct of the race as the ideal of beauty in Woman, and since no lasting ideal of beauty can survive unless it is founded on the truths of natural laws, it would seem that the Venus de Milo most nearly represents the ideal figure of Woman because she is the best representative of a woman in whom all the muscles have been permitted free, harmonious development, and in whom all the internal organs have remained in place.]

## OVERGROWTH OF THE EPIPHYSIS OF THE LOWER END OF THE FEMUR WITH AN OBLITERATION OF THE EPIPHYSEAL LINE.

BY JAMES WARREN SEVER, M.D.,

*Junior Assistant Surgeon, Children's Hospital, Boston; Member American Orthopedic Association.*

EPIPHYSEAL injuries are not rare, and the literature abounds with reports of cases. However, these cases are almost invariably those in which the condition was caused by trauma, — such as fractures, — a violent muscular action causing epiphyseal separation, or due secondarily to acute inflammatory conditions such as osteomyelitis or tuberculosis. There may also be epiphyseal anomalies due to congenital defects.

I have been unable to find just such a case as I am about to report; that is, an apparently idiopathic obliteration of the epiphyseal line, accompanied by a marked overgrowth of the external condyle of the lower end of the femur in a child of eight years. MacAusland [1] reports a case in a child of thirteen years, following a crushing injury to the right knee, which presents features somewhat similar to this case, except in its causation. Coolidge,[2] Feiss [3] and O'Reilly also report cases of epiphyseal injuries which resulted in shortening and deformity. Stone [4] reports cases of deformity and lack of growth following infective processes of the epiphyses. Meisenbach [5] shows by experiment on rabbits the effects of clinical and mechanical stimulation on the epiphyseal and diaphyseal lines.

The history of the case is as follows:

B. N., colored. On Oct. 13, 1902, at the age of three months, the child was brought to the Out-Patient Department of the Children's Hospital for the correction of a right congenital talipes equinovarus. Massage and stretching was advised, which was done until Dec. 10, 1902, when no great progress having been made, tenotomies were done on the plantar fascia, tendo-Achilles and astragalo-scaphoid ligaments, and the foot put up in plaster, which extended to above the knee, which was flexed at about 60°.

On Dec. 24, 1902, the plaster was removed and re-applied, on account of a deep slough above the patella and over the lower end of the femur and extending across the leg. After this the leg and foot were kept in plaster, with frequent changes, until Jan. 6, 1904. At this time the club foot was corrected, but there was considerable atrophy of the foot and leg. No deformity at the knee was noticed at that time. On June 14, 1905, about a year and a half later, she was brought to the clinic on account of the marked outward bowing of her right leg, with an extremely relaxed condition

merly, the greater part of the shortening being in the femur. There was a bad outward bowing, with a marked relaxation of the knee-joint ligaments and a much enlarged external condyle. The tibia was rotated inward, and the patellar tendon formed a marked bow string on the inner aspect of the leg. There was about five inches' shortening of the leg as a whole. The club foot is well corrected, but the foot is shortened and flat. The leg was not very badly bowed except in weight bearing, when it seemed as if there might almost occur a lateral dislocation outward of the femur on

OVERGROWTH OF THE EPIPHYSIS — SEVER

B. 1026. Right leg before operation, April 28, 1910. Showing overgrowth of external condyle, atrophy of internal condyle, change in shape of epiphysis of tibia and absolute obliteration of epiphyseal line on femur except trace on inner side. United at eight years, that is, twelve years before it should normally. Note scar in bone where possibly the osteotome penetrated.

[illegible] of the femur, and apparently well above the epiphyseal line. The leg was corrected, and plaster was applied from toe to groin. This was worn for eight weeks. On getting about following this operation a slight outward bowing of the leg developed, and a bow-leg iron was applied, besides a lift on the shoe to equalise the length of the legs. The child was then lost sight of until Nov. 19, 1906, when she reappeared at the hospital with fully as bad a deformity as before, and slightly more shortening. The parents had left off the brace after a few weeks, and consequently the bow-legged deformity had recurred and increased. A second operation was advised, but was not accepted, and the child was not seen again until March 14, 1910.

The condition at this time was as follows (see x-ray No. 1): The leg was much more shortened than for-

in the epiphysis appearing in the following order. First, the lower end of the bone at the ninth month of fetal life (this is the only epiphysis in which ossification begins before birth, — from this the condyles and tuberosities are formed; in the head of the femur by the end of the first year after birth; in the great trochanter during the fourth year, and in the lesser trochanter between the thirteenth and fourteenth year.

The order in which the epiphyses are joined to the shaft is the reverse of that of their appearance, and their junction does not commence until after puberty, the lesser trochanter being the first joined, then the great trochanter, then the head, and lastly the inferior extremity (the first in

medicine finds two great causes at work in their environment:

(1) (*a*) Structural defects in their framework; leading to weakness and inefficiency, to the development of internal weaknesses and dislocations and to a lowering of resistance to infection.

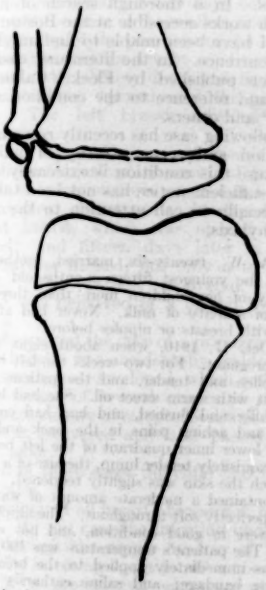
(*b*) Defects in their mental training, leading to lack of balance in mental equilibrium and control, this in turn favoring the development of physical weakness and inefficiency.

Can it be doubted that if this woman escape infection, she can to-day bear and nurse her children as incidentally to a vigorous individual life as did her foremothers?

More and more, the researches of modern medicine show that this is the woman who is struggling to find expression in the Women of To-day.

[It is interesting to observe the resemblance of the synthetic woman outlined above to the Greek statue of the Venus de Milo. Since this Venus

walls, able to support the abdominal organs and the superincumbent weight; with relatively small hips and thighs, well-modeled by muscles and unburdened by superflous fat; and with large, efficient feet, with broad forefeet, long, straight supple toes, firm arches and straight ankles, which sustain and move the whole body, keeping it always in equilibrium.*



* Contrast this figure with the degenerated, so-called "feminine" figure; with the head drooping forward or sideways on a thin, weak neck; the narrow, sloping shoulders; the narrow, flattened chest; the laterally or antero-posteriorly curved spine; the shrunken, retracted lower ribs and waist; the narrow, weak back and loins; the sagging abdomen (revealing displaced or "floating" internal organs); the inefficient thighs, large with impeding fat, but weak in muscle; the bulging inner ankles, with falling arches; the small, weak, splayed feet, with narrow stunted forefeet and distorted toes — all evidences of structural stress, with failing compensation.

shows by experiment on rabbits the effects of clinical and mechanical stimulation on the epiphyseal and diaphyseal lines.

The history of the case is as follows:

B. N., colored. On Oct. 13, 1902, at the age of three months, the child was brought to the Out-Patient Department of the Children's Hospital for the correction of a right congenital talipes equinovarus. Massage and stretching was advised, which was done until Dec. 10, 1902, when no great progress having been made, tenotomies were done on the plantar fascia, tendo-Achilles and astragalo-scaphoid ligaments, and the foot put up in plaster, which extended to above the knee, which was flexed at about 60°.

On Dec. 24, 1902, the plaster was removed and reapplied, on account of a deep slough above the patella and over the lower end of the femur and extending across the leg. After this the leg and foot were kept in plaster, with frequent changes, until Jan. 6, 1904. At this time the club foot was corrected, but there was considerable atrophy of the foot and leg. No deformity at the knee was noticed at that time. On June 14, 1905, about a year and a half later, she was brought to the clinic on account of the marked outward bowing of her right leg, with an extremely relaxed condition of her knee-joint. At this time an operation was advised to correct the bow leg, but was not accepted. There was also considerable shortening of the leg, and the patellar ligament and lower end of the quadriceps tendon formed a bow string across the inner aspect of the leg.

Tracing showing normal epiphysis of left leg of the same child.

An osteotomy was finally done on Jan. 13, 1906, at her home by me. This osteotomy was an external one of the femur, and apparently well above the epiphyseal line. The leg was corrected, and plaster was applied from toe to groin. This was worn for eight weeks. On getting about following this operation a slight outward bowing of the leg developed, and a bow-leg iron was applied, besides a lift on the shoe to equalize the length of the legs. The child was then lost sight of until Nov. 19, 1906, when she reappeared at the hospital with fully as bad a deformity as before, and slightly more shortening. The parents had left off the brace after a few weeks, and consequently the bow-legged deformity had recurred and increased. A second operation was advised, but was not accepted, and the child was not seen again until March 14, 1910.

The condition at this time was as follows (see x-ray No. 1): The leg was much more shortened than formerly, the greater part of the shortening being in the femur. There was a bad outward bowing, with a marked relaxation of the knee-joint ligaments and a much enlarged external condyle. The tibia was rotated inward, and the patellar tendon formed a marked bow string on the inner aspect of the leg. There was about five inches' shortening of the leg as a whole. The club foot is well corrected, but the foot is shortened and flat. The leg was not very badly bowed except in weight bearing, when it seemed as if there might almost occur a lateral dislocation outward of the femur on the tibia. In flexing the leg on the thigh the tibia rotated so that it lay at right angles outward to the long axis of the femur when flexed to 90°.

A linear osteotomy on the inner side of the femur above the adductor tubercle was done on May 10, 1910, and the deformity corrected as well as possible. There was an apparent rotation of the epiphyses outward on the femur, which was also corrected and the leg put up in plaster. The patellar tendon was somewhat tight, but the dislocation of the patella inward could be reduced. The rotation of the lower leg on the femur was also corrected.

The leg was kept in plaster until June 6, 1910, when it was found that the position was not very satisfactory and that there was a tendency to a recurrence, and another operation was considered. The shortening, however, had been decreased from five to four inches. The plaster was omitted and a bow-leg iron fitted with a high sole. In August, 1910, the condition was unchanged. Flexion of the knee was only possible through a few degrees, and there was about 10° of lateral mobility.

The x-ray shows the conditions before operation. The condition to-day is unchanged, and we have a child aged eight years with a very short deformed leg, with an obliterated epiphyseal line and a much overgrown external condyle. The chances are very much against the leg's growing much longer as far as any increase in length in the femur can take place. The tibia may increase somewhat, but will probably lag considerably behind the one of the opposite side. There may occur a very slight growth in the internal condyle from the slight trace of the epiphyseal line which is left, but I do not believe that it will be great or will compensate the present deformity.

It will be of interest to turn for a moment to the study of the development of the femur. The femur is developed by five separate centers, one for the shaft, one for each extremity and one for each trochanter. Of all the long bones, except the clavicle, it is the first to show traces of ossification. This commences in the shaft at about the fifth week of fetal life, the centers of ossification in the epiphysis appearing in the following order. First, the lower end of the bone at the ninth month of fetal life (this is the only epiphysis in which ossification begins before birth, — from this the condyles and tuberosities are formed; in the head of the femur by the end of the first year after birth; in the great trochanter during the fourth year, and in the lesser trochanter between the thirteenth and fourteenth year.

The order in which the epiphyses are joined to the shaft is the reverse of that of their appearance, and their junction does not commence until after puberty, the lesser trochanter being the first joined, then the great trochanter, then the head, and lastly the inferior extremity (the first in

which the ossification commenced), which is not united until the twentieth year.

The epiphyseal line is on a level with the adductor tubercle, but the epiphysis does not form the whole of the cartilage-clad portion of the lower end of the bone. *The growth in the femur takes place chiefly from the lower epiphysis.*

This last fact is all-important in this case. The epiphysis having become obliterated, there can be no more growth of that bone. This brings us to the question of what to do.

There being no epiphyseal or diaphyseal line, we cannot inject substances which might stimulate their growth. Apparently about all to be done is to keep apparatus on the leg to hold it in as good a position as possible, to compensate the shortening by means of a high sole, and to make walking as easy a process as possible. There is no question but what the other leg will keep up its normal growth, and in this way the affected leg will get relatively shorter and shorter. There will be some growth in the tibia on the affected side, of course, but not as much as normal, for disuse or lack of normal use causes considerable atrophy. At present the child is severely handicapped without any great prospect of relief.

The etiology of this condition in this case is not definitely known. From a study of the x-ray and the clinical history rickets and chondro-dystrophy may be ruled out. As the first osteotomy was done about two years after the deformity was first noticed, I fail to see how it could be responsible for it. To be sure, the osteotomy may have been done near or at the epiphyseal line inadvertently, and so may have added to the original condition.

The question of pressure from the plaster cast should be considered, but even were it tight enough to produce a slough over the epiphyseal line, as it did at first, I do not believe it could exert so much pressure on the epiphysis itself as to produce such an after result. The weight and leverage of the lower leg in plaster with the knee fixed and flexed, and the epiphyseal line the fulcrum of this lever movement, may have been enough to have caused a twist and separation of the epiphysis, followed by an overgrowth. This cannot be determined, however, and I question its likelihood on account of the many possibilities it has of occurring with all the club-foot plasters, which are applied in a like manner with no bad effects. The cast, especially when worn for so long as two years, would, of course, lead to marked bone and muscle atrophy.

Any toxic condition can be dismissed from consideration on account of the single joint involved. There were no trophic or other nerve disturbances. There was no syphilitic history, nor any evidence of the disease in this case.

Eventually if the leg becomes so short as to be practically useless it can be amputated and an artificial one applied, which will be far more useful than the present one promises to be.

*N. B.* I am indebted to the X-Ray Department of the Children's Hospital for the x-ray used to illustrate this article.

## BREAST ABSCESS DURING PREGNANCY, WITH REPORT OF A CASE.

BY JOHN T. WILLIAMS, M.D., BOSTON.

BREAST abscess during pregnancy is a condition of which little mention is made in the literature, and which is completely ignored by textbooks of obstetrics. In a thorough search of all recent American works accessible at the Boston Medical Library I have been unable to find any reference to its occurrence. In the literature, case reports have been published by Fleck,[1] Callman [2] and Davis,[3] and reference to the condition made by Billroth [4] and others.

The following case has recently come under my observation and seems worthy of publication, not because this condition is extremely rare, but because sufficient notice has not been taken of it, and especially to call attention to the necessity for prophylaxis.

Mrs. A. W., twenty-six, married, mother of five children, the youngest fifteen months old. Did not nurse any of her children more than three months because of scarcity of milk. Never had any serious trouble with breasts or nipples before.

Seen Oct. 17, 1910, when about eight (calendar) months pregnant. For two weeks the left breast had been swollen and tender, and the patient had been rubbing it with warm sweet oil. She had been alternately chilly and flushed, and had had considerable malaise, and aching pains in the back and limbs.

In the lower inner quadrant of the left breast there was an exquisitely tender lump, the size of a hen's egg, over which the skin was slightly reddened. The right breast contained a moderate amount of watery fluid, but was perfectly soft throughout. The nipples of both breasts were in good condition, and not cracked or eroded. The patient's temperature was 100, pulse 90.

Ice was immediately applied to the breast with a supporting bandage; and saline catharsis was instituted. In spite of this treatment the lump increased in size and became red and brawny. The temperature remained the same. Oct. 21, under ether, a small incision was made into the mass and two drams of pus evacuated. A gauze wick was inserted and a dry sterile dressing applied. The temperature fell at once to normal; the discharge decreased rapidly and the wick was omitted on Oct. 26.

Oct. 27 the lower hemisphere of the opposite breast became "caked" and tender, and the patient's temperature shot up to 102.5. Under ice and salts, this breast softened up rapidly; but, two days later, the left breast again became "caked," this time along the axillary border. The temperature, which the day before had dropped to normal again, rose to 102.5. Ice was again applied to the left breast, which this time subsided rapidly, and by the end of a week both were soft and non-tender throughout, and all treatment had been omitted. It is extremely problematical whether the patient will be able to nurse, and, indeed,

the wisdom of allowing her to attempt nursing is questionable.*

Billroth,[4] among 56 breast abscesses, found 4 during pregnancy; Nunn,[5] 7 among 72; Bryant,[6] 2 among 102; Velpeau,[7] 12 among 200; and Fleck,[1] 1 among 40: a total among 470 breast abscesses of 26, or 5.5%, occurring during pregnancy. In the 230 cases reported by the first three of these writers, there were 34 cases, or 14.7%, which had no connection with either pregnancy or lactation. Schroeder [8] found, among 4,000 deliveries, in v. Winckel's clinic, 6 instances of mastitis during pregnancy, and in 3,600 patients delivered at Marburg, only 5 cases.

Fleck [1] reported the case of a primigravida who developed facial erysipelas during the ninth month, but recovered. A few days before labor, both breasts became red, swollen and painful. On the first day of the puerperium she had a rise in temperature and the breast condition became aggravated. An abscess developed in the right breast, which was opened, and the patient recovered. The left breast subsided without operation.

Callman [2] reported a case of double mastitis during the sixth (calendar) month of pregnancy, the result of infection from eczema and impetigo of the nipples. Fluctuation developed first in the right breast, which was opened and pus evacuated; and fifteen days later in the left, which was also incised, but only a turbid fluid obtained. The patient recovered, went to term and was delivered of a breech by manual extraction.

Davis [3] reported the case of a primigravida, one of whose breasts was accidentally scalded by hot coffee. An abscess developed, which was incised, with the escape of several ounces of pus, from which a pure culture of streptococci was obtained. The patient recovered and later passed through a normal labor.

In each of these cases the child had to be fed by the bottle.

The etiology of all breast abscesses is, of course, infection. In my case the infection undoubtedly entered through the nipple by way of the milk ducts. The infecting agent found a good culture ground in a pre-existing engorgement of the breasts, and its growth and distribution was still further enhanced by hot applications and massage, which the patient applied vigorously before she was first seen.

In Fleck's case it seems most probable that the nipple was here also the portal of entry, although the blood stream cannot be ruled out. Callman's case is an undoubted instance of infection through the nipple, the organisms, however, probably traveling by the lymphatics rather than the ducts. In Davis's case there was no visible solution of continuity at the site of the burn, and the most satisfactory explanation is that the streptococcus was already present in the milk ducts, and attacked the tissues when their resistance became lowered by the burn.

It is unfortunate that no cultures were taken, except in Davis's case, which showed pure streptococcus. Rubeska [9] has shown that the staphylococcus aureus and albus are the most common causes of mammary abscess, the streptococcus being relatively rare. Köstlin [10] found the staphylococcus albus on the nipple in each of 100 pregnant women. In 23 of these the staphylococcus aureus, 25 the streptococcus, 14 sarcinæ, 3 staphylococcus citreus and in 2 the micrococcus tetragenus were also present. He examined the fluid from the breast in each of these cases and found it to be sterile in 14%. In the other 86% the staphylococcus albus was present, and in 2% the staphylococcus aureus as well.

That engorgement of the breasts plays a predisposing part in the etiology of abscess during pregnancy is shown by the fact that in 3 out of 4 cases there was some trouble in the opposite breast, although 2 of these quieted down without incision.

The steps in the formation of a breast abscess during pregnancy appear to be as follows: Organisms are present on the nipples and in the milk ducts of the majority of women, in greater or less number, according to the patient's habits of cleanliness and care of the nipples. These are ordinarily innocuous. When engorgement occurs, conditions favorable to their growth are developed, and when the resistance of the breast tissues is still further lowered by injury, or when organisms of unusual virulence are present, the tissues are attacked and suppuration takes place.

The prophylaxis of breast abscess during pregnancy is the same as during lactation, i. e., absolute cleanliness of the nipples, and the prompt treatment of mastitis by bandage, ice and saline catharsis.

## CONCLUSIONS.

1. Five and five-tenths per cent of all breast abscesses occur during pregnancy.

2. Organisms are present on the nipples in 100%, and in the milk ducts in 86% of all pregnant women.

3. When their growth is predisposed to by engorgement, or the resistance of the breast tissues is lowered by injury, or the organisms present are of unusual virulence, they attack the tissues and produce inflammation.

4. The prophylaxis of breast abscess during pregnancy consists in:

(1) Absolute cleanliness of the nipple.

(2) The prompt treatment of mastitis by bandage, ice and saline catharsis.

* The patient was seen by me again Dec. 17, 1910. She was delivered Dec. 1 in the Out-Patient Department of the Boston Lying-In Hospital. On the fifth day, she stated, the left breast became painful and tender, but rapidly quieted down under ice and saline catharsis, and had given no trouble since. She was nursing her baby on both breasts, although the milk supply was somewhat scanty and the child required supplementary feeding.

## Clinical Department.

# REPORT OF A CASE OF THE ADMINISTRATION OF ONE EIGHTH OF A GRAIN OF MORPHINE TO A BABY TWO AND ONE-HALF DAYS OLD. RECOVERY.

BY NATHANIEL R. MASON, M.D., BOSTON.

THE mother of the patient to be considered was twenty-eight years of age and a native of Russia. She had had four full-term children previously. This child was delivered normally at 1 P.M., Oct. 6, 1906, after a labor of four hours and forty minutes.

The baby was a male and weighed 8¾ lb. He was well developed and vigorous, crying lustily at birth.

The mother suffered from after-pains following her delivery and was given morphia for their relief. When I made my visit on the afternoon of the second day following the delivery, I left two tablets, each containing one eighth of a grain of the sulphate of morphine, to be given to the mother in the evening in case of severe after-pains. As the baby was constipated, I left also six tablets, each containing one tenth of a grain of calomel, to be given to the baby at fifteen-minute intervals.

Early in the evening the nurse retired to rest and a member of the family was left in charge of the mother and baby. The instructions were to begin the calomel at 8 P.M., but the tablets were lost. Feeling that the baby ought to have some sort of medicine, the relative gave him, at 9 P.M., Oct. 8, fifty-six hours after birth, one of the tablets of one eighth of a grain of the sulphate of morphine which had been intended for the mother. The nurse discovered the error about 10 P.M. and immediately telephoned to me. When I arrived at the house at 11 P.M. I found the baby of a somewhat dusky color, lying in a stupor, with a pulse of 128, of poor quality, and respirations of 32. It was stated that the baby had been quiet since taking the morphia and had not vomited. At 11.15 P.M., 15 minims of wine of ipecac were given by mouth. The baby swallowed it with difficulty, but emesis was not produced. The general condition of the baby failed steadily during the night. The pulse became of still poorer quality and rose in rate until it had reached 160 at 3.30 A.M. The respirations were irregular, varying between 6 and 60. The facies became more dusky, and there were periods of cyanosis of five to ten minutes in duration. The baby remained in a stupor. During the ten and one-half hours following the administration of the morphia, the following medication was carried out:

*October 8:*

| | |
|---|---|
| 11.15 P.M. | Wine of ipecac, minims xv. |
| 11.45 P.M. | Sulphate of atropine, gr. 1-350, subcutaneously. |

*October 9:*

| | |
|---|---|
| 12.10 A.M. | Sulphate of strychnine, gr. 1-240, subcutaneously. |
| 12.45 A.M. | Brandy, minims xxx. |
| 1.10 A.M. | Soap suppository. |
| 1.30 A.M. | Suds and glycerine enema. |
| 1.35 A.M. | Sulphate of atropine, gr. 1-350. |
| 2.15 A.M. | Black coffee, oz. iv, by rectum. |
| 2.45 A.M. | Brandy, minims xxx. |
| 3.25 A.M. | Brandy, minims x. |
| 4.15 A.M. | Brandy, minims iii. |
| 6.00 A.M. | Sulphate of strychnine, gr. 1-240. |
| 7.15 A.M. | Brandy, minims iii. |
| 7.30 A.M. | Castor oil, dram i. |

After 9 A.M., Oct. 9, the periods of cyanosis increased in duration and the respirations became very shallow, varying between 4 and 50 per minute, and at times stopping for periods of five to fifteen minutes. At these times artificial respiration was constantly carried out. Oxygen was begun at noon, but no benefit seemed to be derived from it. The baby could no longer swallow. During the afternoon the baby continued to fail. The pulse ranged between 150 and 160 and was barely perceptible at the wrist. The attacks of cyanosis with the accompanying cessation of respiration continued. At other times the breathing was shallow and irregular, varying between 70 and 80 per minute. There was an attack of profound cyanosis and absent respiration for one hour between 3.15 and 4.15 P.M., during which period artificial respiration and the administration of oxygen were constantly employed. A suds and glycerine enema was given at 5 P.M., but no result was obtained. After 6 P.M. a slight improvement was observed. The baby begun to open and shut his eyes. At 7.10 P.M. he gave a faint cry and several others soon followed. At 7.15 P.M., nearly twenty-four hours after the ingestion of the drug, there was a response for the first time to external stimulation, for on pinching the cheek the head was turned away. The pulse improved in quality and dropped to 136 in rate. The respirations remained rapid and irregular, varying between 36 and 72, but they became less shallow. At 10 P.M. 2 drams of castor oil were taken by mouth, the first time the baby had swallowed anything for fourteen hours. Ten minutes later strychnine sulphate, gr. 1-240, was given subcutaneously, as the baby had by this time a pulse of 160 of extremely poor quality. Five minutes afterward twitchings of the face begun and lasted for half an hour. There were several attacks of cyanosis, lasting five to ten minutes, during this second night following the ingestion of the morphia, but there was a gradual improvement in the general condition of the baby. There was a final attack of severe cyanosis between 2.35 and 2.45 A.M., and after that the condition of the baby improved steadily. At 2.45 A.M. the baby vomited half a dram of brownish fluid. This was followed by more vomiting of a similar fluid fifteen minutes later. He began to take albumen water by mouth. The color became excellent and the cry steadily stronger. Evidence of the passing of urine from a moistened diaper was observed for the first time at 5 A.M., thirty-two hours after the ingestion of the morphia. At 6.45 A.M. half a dram of breast milk from the mother was fed to the baby by a spoon and continued at frequent intervals in increasing doses during the day.

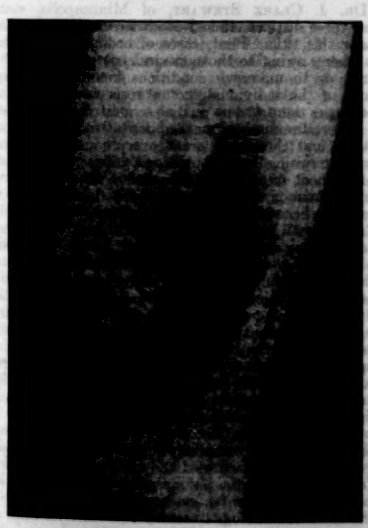
At 11 A.M. the baby had a movement of green meconium, the first passage from the bowel since taking the drug, thirty-eight hours before. At 8 P.M. the baby was started on a milk formula consisting of fat 2.00, sugar 5.00, proteid .75, which it took well at two-hourly intervals in one-half ounce doses.

From this time on recovery was uninterrupted and a few days later the baby was in excellent general condition.

I desire to express my hearty appreciation of the valuable advice of Dr. Leo V. Friedman and Dr. Howard H. Smith, who saw the baby in consultation. I also wish to acknowledge my deep obligation to Dr. Daniel F. Mahoney who on two occasions relieved me in my vigil for a period of several hours, and by his untiring efforts helped to make the recovery of the baby possible.

This unfortunate accident illustrates well the extreme caution which should be employed in leaving a drug to be taken by the mother of a newborn infant.

## KERATOSIS FOLLICULARIS.



BY ARTHUR P. PERRY, M.D.,
*Assistant Dermatologist, Boston City Hospital.*

The occurrence of this disease is so unusual as to make it worth while to report when it is observed. So rare is it that Stelwagon (fifth edition) claims that only twenty-four cases have been recorded, two among the first being those of J. C. White. Bowen has also reported one. Most frequently the lesions appear on the head and face. In this instance, however, these parts have not as yet been invaded. The following is a description of my case:

Miss K., seventeen years old, a high school pupil, was sent to me by Dr. George H. Ingalls, who had treated her for some time without avail. The patient is a rather slight brunette of medium size and attractive appearance. She has never been ill with anything but the usual exanthemata of childhood. Her parents are people in good health and moderate circumstances.

Section of lesion.

Lesion in bend of elbow.

For some years past, brownish areas have appeared in various places on her body and limbs; in the bend of the right elbow, on the anterior surface of the left leg two inches below the patella, on the abdomen in the median line below the umbilicus, and recently one is beginning to show on the neck just below the edge of the collar. These areas are of varying size, up to one or two inches in diameter, of irregular outline, and present the appearance of patches of dirt on the surface of the skin, being yellowish-brown or a darker shade of the same color. On examination, these are found to be appreciably elevated above the surrounding skin. There is no discharge or odor; there are no subjective symptoms. They grow very slowly; at first there is apparent only a deeper pigmentation of the skin, but some weeks or months later the patches assume a rough nutmeg-grater appearance and feel rough and hard to the touch. A biopsy was made for the pathological department of the Boston City Hospital which returned the following report:

"Microscopic examination of sections through one of the small lesions shows moderate elongation of the papillæ of the corium, marked thickening of the horny layer, which is piled up in loose flakes on the surface; slight thickening of the prickle cell layer in places and apparently a slight pigmentation of the lower layers of the epidermis. No inflammatory infiltration of the corium, no obstruction of mouths of sebaceous glands, no dilatation of blood or lymph vessels."

The accompanying photomicrograph illustrates this condition, while the photograph shows one of the larger lesions, though not as clearly as could be desired its rough elevated character. Treatment with various local remedies was without permanent effect. Ung. acid. salicylici, Emplast. acid. salicylici, Ung. resorcin, Dil. potass. hydrat., Sapo viridis and even curettage were employed in turn, but served only to improve the

appearance of the patches temporarily. Excision was considered, but abandoned as impracticable on account of the probability of the recurrence of the disease beyond the borders of the incisions and the disfigurement of the scars. Liq. potas. arsenitis was used internally for a long period.

A course of treatment with radium in the x-ray department of the Boston City Hospital resulted in improvement of the condition of the area treated, the patch becoming thinner and assuming a more normal color. I am convinced that had this treatment been carried out with regularity for some months, definitely good results would have been attained, but the patient moved away to another city, and the case was lost sight of.

## Reports of Societies.

### WESTERN SURGICAL ASSOCIATION.

TWENTIETH ANNUAL MEETING, HELD AT CHICAGO, ILL., DEC. 19 AND 20, 1910.

THE President, DR. JOHN P. LORD, Omaha, Neb., in the chair.

#### DESMOID TUMORS OF THE ABDOMINAL WALL AFTER OPERATION.

DR. E. WYLLYS ANDREWS, Chicago, said he had seen only two cases of desmoid tumor in several thousand abdominal operations, both of which followed herniotomies. The rarity of this complication made it worth while to report these two cases. Most of those so far on record were of another type and followed pregnancy or injury of the fascia above the inguinal region. Keloid was distinct from desmoid in belonging to the skin. Although originating in scar tissue, as after burns or wounds, it always remained movable with the skin, and grew outward, not into the deep fascia. True desmoids were found not in the skin or external cicatrix, nor in the muscles, but in the fascia and aponeurosis, especially of the abdominal wall. Nearly all the reported cases had been in women after repeated childbirth. Histologically desmoid tumors were pure fibromata of the hard white form, like fibromata of the other parts, showing coarse whorls of cut fibers macroscopically like uterine myomata, and spindle cells microscopically with numerous fibrillæ between. The cells showed oval nuclei. Myomatous and even malignant degenerations might occur, as in similar growths elsewhere, but commonly they were benign. Desmoid tumors should be removed by operation inasmuch as the tendency was to grow larger and occasionally to start degenerative retrograde or malignant changes. Dr. Andrews then detailed the two cases that had come under his observation.

#### DISCUSSION.

DR. J. CLARK STEWART, of Minneapolis, said the point of greatest interest in Dr. Andrews' report was the analogy which he possibly showed between this class of tumors, desmoid tumors, as to etiology with keloid. Keloid arose largely from scar tissue. If they could show that any class of fibroid tumors also arose from the seat of traumatism, it would be an important point in their etiology and in their analogy to keloid. He doubted whether the term "desmoid" should be used. Desmoid was an old clinical term which meant just one thing to him and he thought it should be reserved for that one thing because it had no clear clinical or pathological meaning disassociated from that one clinical condition. Originally desmoids were tumors of the posterior sheath of the rectus muscle and he must differ with Dr. Andrews that these tumors were found in the majority of cases in the upper part of the abdomen. The majority of the reported tumors he had run across had been found in the lower half of the abdomen and both pathologically and clinically they had very marked characteristics. Clinically they grew inwardly, so that ultimately they became covered only by peritoneum. They attained considerable size. Quite a number of the reported cases of desmoid tumors were undoubtedly sarcomatous and it was hard to differentiate a sarcoma under the microscope from the ordinary desmoid, and the after-history of these cases had shown several times they were sarcomas, yet he did not think there was any question about the malignancy of desmoid tumors as originally described.

DR. A. E. HERTZLER, of Kansas City, Mo., stated that he thought it was easy to fix the pathogenesis of these desmoid tumors. Any tissue like the fascia of the external oblique, or any tissue which contained a large amount of the original substance, would, when irritated long enough short of suppuration, give rise to this fibrous tissue hyperplasia. One saw the same tumors subperitoneally about the abdomen. They were histologically very much the same. Histopathologically they differed from fibroma in that they were long, with large, oval, vacuolated cells, many round cells and polynuclears. This point was sufficient to separate the desmoid tumor from the fibromatous tumor or any tumor analogous to sarcoma.

DR. ANDREWS, in closing, stated that as to the identity of keloid with desmoid, that keloid, although it appeared in scar tissue, never involved anything but skin. Keloids were confined to the skin, no matter how great the size they might attain, and were movable and free.

#### NON-SUPPURATIVE OSTEOMYELITIS.

DR. J. CLARK STEWART, of Minneapolis, stated that three distinct clinical conditions might be classed under this title. First, cases of ordinary osteomyelitis where, owing to the non-virulence of the invading germ, or to unknown conditions increasing in resistance of the individual, no necrosis was caused. In such cases there was no pus, no sequestrum, but instead in a certain number marked irritative reaction was set up and there was great overproduction of bony tissue resulting in a thickened, dense and painful enlargement of the bone attacked. These cases were quite common, regularly recognised and properly treated. Second, cases of injury, generally fracture, where a small piece of bone was entirely separated and died, forming about it a closed cavity of dense new bone in which it lay until absorbed but without suppuration. These cases differed entirely from those of the first class in that the irritant which caused new production of bone was not bacterial, or at least not primarily so, but a fragment of bone which remained practically aseptic. The third class, and the one to which he especially wished to call attention, differed entirely from both of the above by having no notable beginning, but an insiduous onset although a febrile illness and a slight injury respectively antedated by two years the culmination of the disease by surgical interference. The disease was essentially chronic but progressive and regularly misdiagnosed and treated as rheumatism. He had only seen the lesions present in the tibia, but this must be accidental, as it might as well occur elsewhere. The etiology seemed absolutely wanting, as the two cases narrated had nothing in common, while the pathology and symptomatology were identi-

cal. This third class seemed to be of a different type of chronic osteomyelitis not recognized by the text-books on surgery, the nearest approach to a description of them being called "chronic osteoperiostitis," which was certainly a misnomer, for in these cases the periosteum was regularly normal. Their characteristics pathologically were the transformation of the marrow cavity into a multicellular labyrinth filled with a tissue which macroscopically resembled red marrow. There was also a synchronous subperiosteal production of bone which resulted in a fusiform enlargement, the new bone being spongy and not dense. Symptomatologically they were characterized by insidious onset, so-called rheumatic pains, worse in damp weather and at night, with slight evening rise of temperature. While the two cases cited each gave a history of an acute causative agent, in neither could this be said to stand in an undoubted etiologic position, as the local symptoms in both cases occurred over two years later. What would ultimately happen to a case of this kind without operation could only be surmised. Neither case showed any apparent change during the several months it was under observation and it seemed probable that the bone would merely remain enlarged and painful until stirred up by a fresh injury or infection, when there would be suppuration and a sinus would be formed.

The diagnosis was easy after syphilis was excluded by the non-effect of the iodides. Tubercular osteomyelitis regularly caused cold abscess and sinus formation, while periosteal sarcoma was generally more rapid and could be eliminated by the use of skiagrams. Fusiform enlargement of a long bone, increasing very slowly in size with point pressure, tenderness in various places over the enlarged bone, and slight afternoon temperature, gave a characteristic picture. The treatment was opening the bone and following the morbid process each way until normal bone was reached, cleansing, drying and filling the cavity with Moorhof's wax or union by first intention.

Dr. D. S. Fairchild, of Des Moines, Ia., stated he had seen a number of cases of this kind which seemed to have arisen from trauma or some injury which had been inflicted to the bone, with involvement of the periosteum to some extent, but the trouble seemed to extend throughout the entire shaft of the bone, the tibia being most commonly affected because it was more subject to traumatic influences. In the cases that had come under his observation the bone had been dense; that was to say, if the condition had existed for a long time, the bone became dense throughout its entire extent. In the young cases where the disease had not been progressing for a long time the bone was softer, and when the medullary canal was examined it was found almost entirely occluded by the proliferation of this bony tissue. These cases it seemed to him were more like cases of osteitis in which the inflammation had extended not only into the medullary canal and from the periosteum, but into the bone substance itself, and in the cases of long standing the bone had been very dense so that when a gutter was tunneled out, it required a considerable amount of chiseling to do so. While these cases were not very common, yet they were common enough to constitute a matter of very considerable interest to the medical profession.

Dr. W. W. Grant, of Denver, stated the diagnosis of the pathological condition under consideration was not made early, and that is why they did not see more of these non-suppurative cases of osteomyelitis. It was his opinion that if they would give them time, there would be ultimately death of the part and either pus formed or sequestrum and an involucrum. They saw these cases formerly much oftener than now, because no one thought of operation until there were several sinuses leading to the canal. That was the usual method of dealing with these cases. To-day the diagnosis could be made earlier, and if it was, operation should be done earlier when the patient would be saved several months and years of suffering, and would finally get well with a better leg and a better looking leg. It was necessary to exclude syphilis and tuberculosis especially in arriving at a proper diagnosis.

Dr. James E. Moore, of Minneapolis, stated that the principal difficulty in diagnosis was between non-suppurative osteomyelitis and chronic bone abscess. Therapeutic tests would eliminate syphilis. As a rule, syphilitic disease of the bone was bilateral, while non-suppurative osteomyelitis was usually unilateral. Chronic abscess of bone was likely to be limited to one end of the diaphysis, while the condition they were discussing affected the whole diaphysis. The history of these cases was that of a low form of inflammation, with gradual enlargement, the principal symptom being pain, more particularly at night. When they came to operate upon these cases they found the main part of the bone proper was eburnated, and the older surgeons amputated many of these limbs, showing how great the pain was at times. The modern treatment was that pointed out by the essayist.

Dr. Arthur T. Mann, Minneapolis, stated that in the last six months he had had two cases of this type of osteomyelitis in which he had used the Moorhof wax. One patient was a girl, thirteen years of age, who had symptoms for two years. She had been kept under observation as a charity patient by another physician, who spoke to Dr. Mann about her six months before he saw her. She had the usual symptoms of osteomyelitis in the lower third of the tibia, the pain being worse at night, and the temperature running up to 102 at times, but as a rule it was not as high as that. At the end of two years, when he saw her, she had a fusiform swelling at the junction of the lower third of the tibia which was very tender. She cried at night on account of the severe pain. On opening this there was a mass more dense than cancellous tissue, but much thinner than ordinary cortical bone, so that the cortex had thinned out and the medullary cavity had filled in. In the center of this there was pale granulation tissue. This condition lasted two years. This tissue was scooped out and the cavity filled with Moorhof's wax, and the usual closure of the wound made. There was healing by first intention. The pain stopped immediately following the operation. This was a case in which there had never been suppuration.

Dr. William H. Magie, of Duluth, Minn., said he would like to speak of a form of treatment which he adopted in a recent case. In this case the bone had been previously troughed by himself. Recurrence took place four or five months later, when Dr. Judd, of Rochester, Minn., operated. Later the patient returned to him with all the symptoms re-established. At the examination he found the tibia for fully eight inches enormously enlarged, so that the case really looked like one of sarcoma. He adopted the plan of not troughing the tibia, but chiseling down at the extreme end of this enlargement, splitting it, removing one half of the tibia, then he applied skin direct upon the raw surface of the bone that he had left, after removing half of the diameter of the tibia fully eight inches in length. The wound healed perfectly by first intention, and the pain was relieved immediately. The patient had been well since and was working at his occupation in the woods as a foreman of a lumber crew of loggers.

Dr. A. E. Hertzler, of Kansas City, Mo., said that in arriving at the pathogenesis of this condition he

did not think they would made a mistake if they called it a desmoid tumor of the bone. If the tumor in Dr. Andrews' case had occurred in the medullary cavity the patient would have had this trouble they were discussing. In the chronic sclerosing type of bone disease they had a milder form of infection which produced an exudate which was capable of being organized, and not as in the more acute types which form an exudate which was not all organized. These conditions could be rather clearly followed out if one took the trouble of applying tinctorial chemistry to these various tissues. Rather unconsciously, he suspected, in the use of Moorhof's bone plug they were imitating in a measure a very mild type of infection. The iodoform produced an exudate which was capable of being thrown down into a fibrillar type of fibrin, and it was by active hyperemia acting on the substance which produced an exudate, after forming this type of fibrin, that healing was brought about.

DR. M. L. HARRIS, of Chicago, stated that in the cases belonging to the subgroup which had been described by the essayist, there was no material enlargement of the bone. There was no condensation of the bony cortex. The disease usually affected the shaft of the bone. In the interior of the bone they found the red marrow which Dr. Stewart mentioned. It was very soft, almost semiliquid in some cases. These cases were characterized by extreme pain. The most interesting and typical case of that kind he saw was a man who had been treated for syphilis. He had visited several watering places in Europe, but returned to this country without being relieved. His pain was so severe that he was obliged to take morphine to afford relief. There was extreme pain in the shaft of the humerus. These cases were sensitive when the bone was percussed by hammer or when deep pressure was made. All that was necessary to do in such cases was to open the medullary cavity, remove a portion of the cortex, relieve tension, and these cases recovered.

### PRIMARY SARCOMA OF THE APPENDIX.

DR. EVERETT O. JONES, of Seattle, Wash., said that primary sarcoma of the appendix was an extremely rare condition. He detailed a case on which he had operated successfully, and then drew the following conclusions: (1) An accurate diagnosis before operation appeared to be impossible. In every case the symptoms were those of some type of appendicitis. (2) Pathologically the round-cell sarcoma predominated, next to this the spindle-cell type. (3) Inflammatory changes either chronic or acute very frequently accompanied the growth. (4) The immediate prognosis and prospect of freedom from recurrence were very good. (5) The fact that primary sarcoma of the appendix that took its origin in an inflammatory process occurred, formed a very strong additional argument for the removal of all appendices which showed evidences of inflammation.

### DISCUSSION.

DR. A. E. HERTZLER stated he had no hesitation in referring to this case as one of desmoid of the appendix, because he did not know what a desmoid was, and he did not know the nature of the appendix the essayist removed in this particular case. It was common to have microscopic pictures in these chronic gut inflammations which looked very much like sarcoma; hence the greatest care possible was necessary to make the differentiation.

DR. S. C. BEEDE, of David City, Neb., said before hearing Dr. Hertzler's remarks he was under the impression that primary sarcoma of the appendix was a surgical curiosity, but now he was not sure that it was even a curiosity. Ever since Warren reported his case in 1898 there had been considerable investigation carried on with a view to finding malignant disease of the appendix. In the department of pathology of St. Mary's Hospital, Rochester, Minn., of 5,000 appendices removed for disease, there were only 22 cases of carcinoma of the appendix, and not a single case of primary sarcoma of the appendix developed.

DR. WILLIAM C. MCCARTY, of Rochester, Minn., stated that he had had the privilege of examining about 5,000 appendices which were removed in Rochester, and since that investigation was made he had extended the list to about 10,000, and in all this series he had not seen one of sarcoma of the appendix. In the first 5,000 cases examined, as Dr. Beede had just stated, there were 22 cases of carcinoma of the appendix. Two of these he had previously diagnosed as endothelioma, which showed that the differential diagnosis between endothelioma and sarcoma was a difficult one. These were all very early cases, and in only 1 out of 17 was the serosa involved.

DR. DONALD MACRAE, of Council Bluffs, Ia., stated he had had eight or ten cases which from macroscopic appearances and the sensation imparted in his fingers appeared to be sarcoma of the appendix, yet he agreed with Dr. Hertzler. Unfortunately in the cases he had had the disease was not entirely confined to the appendix, but involved the cecum, and there were adhesions which tore away like frozen meat, and the mass had a sarcomatous feel.

DR. ARNOLD SCHWYZER, of St. Paul, Minn., stated that a few years ago, while on a visit to Switzerland, a patient presented himself with a large tumor of the diaphysis of the femur. Professor Kocher was to operate on this patient, believing the tumor was malignant. Sections were taken from it and examined by Professor Langhans. These sections had to be frozen as a quick report was necessary. Professor Langhans made the positive report that the tumor was a round-cell sarcoma. In the meantime, while waiting for the report, Kocher observed the tumor and found some grayish little dots here and there which appeared to him to be deteriorated tissue, and came to the conclusion that it was a case of infectious granuloma. He acted accordingly, left the femur, and saved the patient's leg. No recurrence took place. It was difficult to make a differentiation between infectious granuloma and sarcoma.

DR. EMERSON F. ROOT, of Salt Lake City, stated that about six or seven years ago he had a case of what he thought was primary sarcoma of the appendix. The patient had had a chronic appendicitis for more than a year. He refused operation, and at this time for a month or two he was rapidly running down, and asked to be operated on. Operation was performed. The appendix was found to be very large, five or six inches long, and an inch or more in diameter, with its lumen almost occluded. It was rather hard and very loosely attached. The cecum was not involved to any great extent. The appendix was removed together with a small portion of the head of the cecum. The wound healed by primary intention. Two or three months later the patient died. In this case the microscopic diagnosis was made of round-cell sarcoma of the appendix.

DR. WILLIAM JEPSON, of Sioux City, Ia., stated that he was adverse to coining new terms that did not express anything. The term desmoid tumor arose from the fact that prior to their histological conception of what these tumors were like, they were classed as having developed from hard band-like masses found in the rectus muscle or else in the transverse fascia. The term desmoid meant hard band, and these hard bands

were found in the abdominal wall, and it was found tumors developed from them, and consequently they were called desmoids. Was there any reason why they as surgeons should adhere to such a term when these tumors were strictly fibromas? That was all they were.

Dr. Jones, in closing, said he regretted he did not bring the sections along with him. He would say, however, that these sections were submitted to four or five pathologists in his neighborhood and all of them pronounced the disease sarcoma.

### ACUTE SUPPURATIVE APPENDICITIS.

Dr. Willard Bartlett, of St. Louis, Mo., described the operative technic in this condition at which he had arrived after years of simplification. (1) The abdomen was invariably opened through a gridiron incision immediately over the dull area if one could be made out, otherwise at McBurney's point. It was very rarely the case that this incision had to be enlarged, which could be done though with slightly greater difficulty than was the case in ordinary through and through openings. His experience had taught him that it was just as applicable to pus work as to any other. (2) Immediate search for the appendix was made, it being his practice always to remove it if it could be found without unnecessary loss of time or disturbance of many adhesions in the presence of a large amount of pus. He did not often go so far as to turn out the head of the cecum in order to find the appendix, but considered this advisable where this carried with it the adherent viscera which completely surrounded a collection of pus, to be opened outside of the abdomen at the removal of the appendix. It was rarely his custom to do much or any so-called walling off with gauze in the search for the appendix. They long ago learned that intra-abdominal tension forces liberated pus toward the opening in the wall rather than in any other direction. On the other hand, undoubted harm was done by gauze packs. At the same time, ready access to the viscera was interfered with. While in clean work he made a peritoneal autoplasty when working on the appendix or any other viscus covered by peritoneum, in these pus cases he simply tied a strand of catgut around the base of it, including the mesenteriolum, and cut it off. Not only did this save time, but the appendix and adjacent cecum were often so indurated and friable that ordinary Lembert stitches would not hold. By way of justifying a search for the appendix in the acute stage, it was hardly necessary to state that a variety of dangerous complications were avoided by its removal. In a very small per cent of these cases a fecal fistula had made its appearance, but not one had failed to close spontaneously in a few days. (3) Drainage was instituted in every case where exudate was met with. This was most readily and accurately accomplished to his thinking by tying at its middle a strip of rubber dam or a ribbon cut from an old rubber glove in the catgut ligature on the base of the appendix mentioned above. This treatment sufficed for ordinary cases, although he was not here dealing with remote pus collections, which were infrequently early in the disease and which must be considered as complications not to be dealt with in any simple routine procedure. Drainage was further aided by placing the patient in bed on the face directly after the operation. In a few days the catgut ligature was absorbed and the drainage came out of its own accord. (4) Suture of the deeper layers of the abdominal wall was never attempted unless the muscle-splitting incision had been considerably enlarged. The drain practically filled the small dead space resulting from the spontaneous closure of such incisions, thus re-establishing intra-abdominal pressure sufficiently for their purpose. In the middle of the skin wound was placed one or two clips, at each side of which one half of the rubber drain emerged, its two ends being fastened together by a clip which prevented the possibility of its being drawn into the abdomen. Thus one had practically coapted the edges of an infected wound without any danger of pus retention in the depths or under the skin. After the two drains had been removed at the end of a week, the resulting defects in the skin were closed with adhesive plaster, and in two weeks after the operation most of these patients were out of bed with a solid abdominal wall and with the skin wound completely healed or almost so.

### SURGERY OF THE MEDIASTINUM.

Dr. B. Merrill Ricketts, of Cincinnati, spoke of the progress that had been made in the surgery of this region. The neoplasms now operated on in this region included abscess, dermoids, lipoma, foreign bodies, hemorrhage, enchondroma, hydatids, etc. Strange as it might seem, the two conditions that had been operated on most frequently were abscess and dermoids. In the last ten years numerous devices had been introduced for positive and negative pressure. There had been nothing done with the Sauerbruck apparatus that could not be done without it, so that there were no special advantages attending its use. In his experience he had found that he could expose the tissues of the esophagus, a bronchus, or any portion of the lung, pericardium, or any portion of the mediastinal space without this apparatus. But surgeons now had something at their command which was of special interest and usefulness, namely, the Matas method of inflation. With this means the chest could now be opened and anything done upon the tissues within it by the method that had been suggested.

### A NEW PRINCIPLE IN THE ACTION OF ANTISEPTICS.

Dr. M. G. Seeling and Dr. C. W. Gould, of St. Louis, Mo., stated that they had developed the idea that effectiveness in the action of a germicide was predicated upon two factors: (1) The inherent power of destroying germ life, and (2) the power of penetrating tissues, blood clot or exudate, in order to reach the bacteria. The fact was emphasized that, as a rule, surgically considered, bacteria were not found free on the body surface, but in the depths, and the problem of reaching them was similar to the problem confronting naval ordnance experts, namely, the creation of sufficient driving force to enable a projector (germicide) to reach the vitals of a war ship (protoplasm of a bacterium). This power of penetration merely expressed the physical and physiological phenomena known as osmosis. They summarized the methods used in the past for testing the efficiency of germicides, and showed that they were all untrustworthy from a surgical point of view, in that the laboratory conditions were not made to conform with those of actual experience. The powers of a germicide had not been thoroughly or correctly tested unless its osmotic properties had been taken into consideration. Their method consisted in subjecting various organisms — typhoid, colon, streptococcus, staphylococcus — to the action of various germicidal solutions. The organisms were used in simple broth cultures and they were invariably separated from the germicide by either a specially constructed celloidin membrane, or by a live animal membrane skin, mesentery, omentum, diaphragm.

The results of the experiments might be summarized as follows: (1) Germicidal drugs, such as bichloride, carbolic, chrysilic acid and lysol, in watery solution of various strengths, had no apparent effect on organisms

that were separated from the germicide by a thin layer of celloidin, an excellent osmotic membrane. Iodine in watery solution was an exception. It osmosed through the celloidin and destroyed the organisms. (2) With animal membranes, excepting a 3% watery solution of carbolic acid, the same results were secured as with celloidin membranes. (3) Alcohol, above 30% strength, penetrated the celloidin membranes with a degree of rapidity and effectiveness proportionate to its percentage strength. Ninety-five per cent alcohol killed the organisms in from three to ten minutes; 80% in about an hour and a half; 70% in about seven hours, whereas 50% did not kill in twenty-four hours. Ninety-eight per cent was not perceptibly more efficacious than 95%. (4) The addition of bichloride or carbolic acid did not increase the osmotic power, or intensify the germicidal action of alcohol. (5) The addition of iodine to the alcohol made a solution of heightened osmotic power and increased the germicidal power. (6) The fatty constituents of the tissues, the skin, for example, rendered them better osmotic membranes for alcohol and tincture of iodine, for the reason that alcohol was soluble in these fats. This phenomenon underlay the fact that thorough washing of the skin interfered somewhat with the germicidal effect of the subsequent application of alcohol. The generally accepted explanation that washing the skin was a disadvantage because it softened and swelled the epidermis, was incorrect.

### DEFINITE KNOWLEDGE OBTAINED BY MEANS OF THE X-RAY.

DR. E. M. SALA, of Rock Island, Ill., reported twenty-two cases illustrating a variety of conditions in which the x-ray proved very useful and decidedly advantageous. His conclusions were: The x-ray, when in good working order, was one of the most valuable adjuncts to good surgical work they had at their command. It helped to make surgery a more exact science; it gave them a much clearer understanding of their cases and would eventually lessen to a great extent the vast number of cripples that were unavoidable previous to the time of its use.

### DISCUSSION.

DR. DANIEL N. EISENDRATH, of Chicago, showed a specimen which was obtained at autopsy of the bladder, ureter and the left kidney with dilated pelvis. In dissecting the specimen several phleboliths were found. These phleboliths lay close to the ureter, entering into the posterior wall of the bladder. He exhibited an x-ray plate showing the progress that had been made in the x-ray diagnosis of ureteral calculi. He emphasized the great value of the x-ray as an aid not only in fractures, but in many other fields of surgery.

DR. WILLARD BARTLETT, of St. Louis Mo., said in regard to wiring fractures which was touched on in the paper, given cases in which an open operation was decided upon, he wanted to speak emphatically in regard to the usefulness of the Lane plate. Since having observed Mr. Lane's work in London about six months ago, he had had occasion to screw on steel plates in from forty to fifty cases, and with the exception of fracture of the patella, of which he had had only one in this series, and with the further exception of fracture near the ends of the long bones, he believed that wire had been driven out of business by the Lane plate.

DR. A. H. LEVINGS, of Milwaukee, Wis., wished to say a few words with reference to the treatment of fractures. He had listened with a good deal of interest to what Dr. Bartlett had said about having put on Lane plates in forty or fifty cases of fractures since he had returned from London six months ago. He had had the pleasure of meeting Mr. Lane in Milwaukee a few weeks ago while on a visit to this country, and discussed with him the question of the universal use of these plates, and he would like to ask Dr. Bartlett whether he did not find it difficult to get patients who would allow him to operate on every case of fracture. He thought any man who had used the Lane plates on forty cases within six months must have operated on every case that had come under his observation. Where fixation was required to immobilize bone fragments that could not be otherwise immobilized, the Lane plates were infinitely better than wire, because most of the members who had examined skiagrams of fractures after they had been wired, especially of the femur, had found in many instances that the wires failed to hold the fragments in approximation, and in some instances the deformity and the displacements of the fragments had been greater after wiring the fragments than before. In regard to spiral fractures of the tibia, they were quite common. For some four or five years he had been treating all these fractures of the lower extremity without wiring, without any mechanical fixation whatever, and he had yet to find a fracture that could not be reduced and held in good approximation without the use of either Lane's plates or wire. With the collaboration of Dr. Mueller, of Chicago, some five years ago he devised an apparatus for the mechanical extension of the leg while a plaster cast for the purpose of immobilization was being put on the leg, and with it he had obtained excellent results.

DR. EMERSON F. ROOT, of Salt Lake City, stated that if you went before a court of justice, every juror, every person in the court room, had an idea of the x-ray picture, and he read it to suit himself and this was not at all in accordance with the idea of the man who took the picture. No man was so wise that he could offhand read every x-ray plate or very many x-ray plates without gradually educating himself to do so, and in going before a court he thought the person who had the x-ray plates to explain should insist on having his version of the matter taken by the jury and by the court.

DR. SALA, in closing, stated that he was a firm believer in the use of the Lane plates, but they would not be a good substitute for the wire in the class of cases he had mentioned.

### PRIMARY SUTURE OF SUBPARIETAL RUPTURE OF THE KIDNEY.

DR. F. GREGORY CONNELL, of Oshkosh, Wis., after reporting an interesting case of simple subparietal rupture of the left kidney in which he resorted to lumbar incision and suture of the kidney forty-two hours after the accident, with recovery, drew the following conclusions: (1) Owing to the rapid, recent increase in the number of reported cases, there was reason to believe that subparietal rupture of the kidney was more frequent than the literature would lead one to believe. (2) Shock injury to other organs and external evidence of trauma were frequently absent. (3) History of an abdominal contusion, followed by rigidity and hematuria, was sufficient to lead to exposure of the organ. (4) Slight lesions and complete rupture of the kidney could not be differentiated by clinical signs or symptoms. (5) Proof of the absence of serious rupture was called for before instituting the so-called expectant treatment. (6) Nephrectomy should be reserved for very extensive disintegration of the organ. (7) Conservative treatment, preferably by suture, was indicated in the majority of cases.

### DISCUSSION.

DR. WILLIAM J. FRICK, of Kansas City, Mo., said heavy blows or falls striking on or about the lumbar

region should always be regarded as serious. The appearance of hematuria following such injury should be sufficient evidence upon which to make a diagnosis of rupture of the kidney, although the absence of hematuria following such injuries is not always absolute proof that the kidney had not been injured. In one case of subparietal rupture of the kidney, a complicated case, hematuria was very slight, although the damage to the kidney was apparently beyond repair. The patient did not live very long. The wound about the kidney was simply packed. Injuries of the kidney were nearly always followed by hematuria, but this was not invariably the rule. In a case of gunshot wound of the kidney there was not a trace of blood in the urine to be found, macroscopically at least, although the perirenal space was filled with blood. When a diagnosis of rupture of the kidney was made, the kidney should be exposed by a lumbar incision, especially if it be an uncomplicated rupture of the kidney, as it was the only means they had of determining the extent of damage done to the kidney. They could not depend upon the amount of hematuria or any other sign. Knowing the ability of kidney tissue to repair itself, they should attempt conservative surgery in these cases. Nephrectomy should not be done unless the injury to the kidney parenchyma was so extensive as to preclude the possibility of saving enough of it to be of functional value, and unless the injury to the renal vessels was so great as to seriously interfere with the nutrition of the organ.

Dr. George N. Kreider, of Springfield, Ill., stated that if he might combine a little remark in regard to Dr. Sala's paper with this one, he would say that with the latest development of the x-ray picture, they could definitely outline the kidney, differentiating the pelvis from the substance of the kidney by the Snook type of x-ray machines. Another valuable item he saw in one case and which might be of advantage also in connection with the x-ray, and that was, to give the patient methylene blue, which would undoubtedly cause staining of the tissues about the injured kidney, and this with the radiogram might prove of great assistance in the diagnosis of these cases.

Dr. B. B. Davis, of Omaha, Neb., thought a great many nephrectomies had been done in the past unnecessarily, and they were beginning to realize the wonderful reparative power the kidney possessed. He had had one case in which he cut off the lower end of the kidney, removing about one third of the organ, and putting in a mattress suture below, with recovery of the patient. He believed that in many of these cases the suture was very much to be preferred to gauze drainage or gauze used to control hemorrhage.

Dr. F. A. Dunsmoor, of Minneapolis, stated that there was one point which might be added to those that had been brought out in connection with this paper, and that was this: It was not the mere escape of blood which produced death in these cases, but it was the mixture of urine with the blood and its absorption into the tissues which caused death, particularly in these complicated cases, in which the abdominal cavity was contaminated.

Dr. Arnold Schwyzer, of St. Paul, stated that as to the diagnosis, blood in the urine might be very scant. In one case of injury to the kidney that came under his observation, the first urine which was drawn with catheter in the hospital was not examined, and this was about two hours after the injury. The first urine they got should not only be examined by the eye, but microscopically.

Dr. A. W. Abbott, of Minneapolis, wished to speak of some experiments which were made by a Minneapolis physician (Dr. J. Frank Corbett) for the purpose of determining the ultimate results of injury to the kidney. In the first place, where the kidney had been injured and the capsule only sewed together, if there was much hemorrhage left in the kidney, it was followed by inflammatory trouble usually, and then by a scar, and a large part of the kidney was rendered useless. The same results followed packing. The best results were obtained by the through and through suture which passed through the kidney directly and about the outer limits of the pyramid. This was followed by less scarring, etc.

Dr. Daniel N. Eisendrath, of Chicago, wanted to endorse the position taken by Dr. Davis in contradistinction to that taken by Dr. Connell and Dr. Frick, and his experience was based on a personal observation of fifteen cases of subparietal rupture of the kidney. The conclusion from the study of these cases had been forced more and more upon him that the more conservative they were in the treatment of subparietal rupture of the kidney, the greater would be their percentage of recoveries, and he thought that was the tendency they saw in the foreign literature of this subject. He had seen some extremely severe cases where he thought he would do nephrectomy, but he had watched these patients bleed and bleed, and by simply leaving them alone they had recovered. Why did they recover? Granted that the kidney was extensively impaired, they knew these patients were not good subjects for operation; they were suffering from considerable shock, and the manipulation necessary to find and grasp the bleeding artery, which perhaps had already become partly or completely occluded by blood clot, and then started up hemorrhage in a fresh field, was attended with more harm than if they let these patients alone. They knew from experimental work on the kidney that if they tied off the renal vessel, and left the kidney *in situ*, that kidney underwent complete atrophy, and within a period of a few months the kidney would be a mass of cicatricial tissue. That condition undoubtedly took place in a certain proportion of cases where the kidney had been severely injured.

Dr. E. W. Andrews, Chicago, stated that he had seen a man with a ruptured kidney on whom he had operated and declined to remove the kidney, because he thought he had successfully ligated the bleeding point, three days afterwards get another severe violent hemorrhage and die within a few minutes. They could not get away altogether from the old teaching that a ruptured kidney was apt to terminate fatally conservatively treated, that was, nothing being done in the way of interference. He did not think they should stand by and let these patients with ruptured kidney have one hemorrhage after another without doing something for them; but it did not necessarily follow that nephrectomy was the only operation of choice in these cases, for sometimes, as he had done in the case of injury to the spleen or liver, they could make a closure operation. In addition to ligating the bleeding points they could close the injured kidney with rows of mattress stitches, and if such an operation was done under aseptic conditions, it might give a percentage of successful results which would compare favorably with nephrectomy as a life-saving measure.

Dr. Walter Courtney, of Brainerd, Minn., wanted to say a word about differential diagnosis between contusion of the kidney and rupture. He had seen a good many cases of injury of the kidney. If the surgeon would wait a few days, as he might in most cases, provided hemorrhage was not alarming and secondary anemia had not taken place, a large number of these cases would gradually clear up, and it would be found that the kidney had only been contused.

DR. JAMES E. MOORE, of Minneapolis, stated that it was only in exceptional cases that a nephrectomy was justified for rupture of the kidney. A patient was brought into the University Hospital recently, thirteen days after he had been thrown in a runaway accident, and presumably had sustained a ruptured kidney. He was brought to them in a moribund condition with his bladder full of clotted blood. He died. At the post-mortem examination they found that he had sustained a rupture of one of the terminal branches of the renal artery just before it entered the kidney, and the presence of blood in the urine was accounted for by the fact that through pressure the blood was transmitted along and had broken through into the pelvis of the kidney at a point below and finding its way down the ureter into the bladder.

DR. DONALD MACRAE, of Council Bluffs, Ia., said it seemed to him it was well to take a middle ground in dealing with injuries of the kidney. If they made a positive diagnosis of post-peritoneal rupture of the kidney or of contusion, the case was not fraught with as much danger as other forms of injury to this organ. But if they found a patient was going to the bad, he thought they should resort to incision, with drainage, or whatever was necessary to be done at the time. It was better, however, not to fuss with the kidney if they could help it.

*(To be continued.)*

## Book Reviews.

*Report of the Commissioner of Education for the Year ended June 30, 1910.* Volume I. Washington: Government Printing Office. 1910.

This first volume of the annual report of the United States Commissioner of Education, Mr. Elmer Ellsworth Brown, contains an immense amount of statistical material, with comment thereon, admirably classified and arranged for comparative study. The fundamental purpose of the report, as stated in the introduction, is "to set forth some of the main features of the American educational program and to point out some of the places at which there is need of improvement. There are chapters on current topics of special interest, on educational legislation, on industrial and agricultural education and on educational methods and advances in other countries. Under the section on health and hygiene it is gratifying to note that Massachusetts leads all other states of the Union in the number of its cities and towns in which physical examination of school children is provided. Massachusetts has such provision in 46 municipalities; New York stands second with 26; New Jersey third with 21; and Pennsylvania fourth with 19. The second volume of this report, which is expected to appear in about three months, will contain further statistical tables and "an account of the Alaska service of the Bureau of Education."

*The Practice of Surgery.* By JAMES GREGORY MUMFORD, M.D., Visiting Surgeon to the Massachusetts General Hospital; Instructor in Surgery in the Harvard Medical School; Fellow of American Surgical Association, etc. W. B. Saunders Company.

Dr. Mumford gives us a single volume of a thousand pages, dedicated "to my friends and associates in the Society of Clinical Surgery." The book is to be praised, and for a variety of reasons; in the first place, it is the work of one man, a young and vigorous surgeon, who for twenty years has made the most of unusual opportunities for observation, study and practice. Furthermore, it is from the pen of a writer, widely known throughout this country and England, whose style is finished, and whose forcible and at times unusual use of the English language holds the attention and fixes his statements in the memory. When one thinks of the average American textbook from the standpoint of a literary production, the relief in turning to Dr. Mumford's pages is indeed very real. Moreover, as John B. Murphy has indicated, Dr. Mumford knows what to omit; and this, added to an equally valuable knowledge of how to condense essential facts smoothly yet clearly has made possible a complete work within the limits of the present volume.

"In this book . . . I give to the reader an account of the practice of surgery — of surgery as he will see it at the bedside, in the accident ward and in the operating-room." This promise made in the preface is conscientiously executed in the text. He considers surgical diseases in their order of interest, importance and frequency, and endeavors also "to lay stress on those subjects which Nature herself has accentuated."

The book is divided into seven parts, with numerous chapters and subheadings. The main divisions are (I) The Abdomen; (II) Female Organs of Generation; (III) Genito-Urinary Organs; (IV) The Chest; (V) The Face and Neck; (VI) The Head and Spine; (VII) Minor Surgery — Diseases of Structure. All of these subjects are discussed vigorously and definitely; in many instances a single operation, the author's choice, is outlined in detail; there may be other good methods of treatment, but he describes the one which appeals most strongly to him. Therefore it follows that wherever the reader may open the book, he will find it attractive and convincing, as well as instructive, for it abounds in accurate positive statements, and is free from vague generalities and hair-splitting discussions.

The illustrations are numerous, in part original, in part adopted. The originals are distinctly good and decidedly above the average; the others are chosen with care and good judgment, and as a deserved compliment to the original artists are carefully and efficiently reproduced. The index seems sufficiently complete.

The volume may be confidently recommended, both to students and practitioners, as one from which they may learn many things pleasantly, and to which they may often return with well-founded anticipations of solace and enjoyment.

*Phases of Evolution and Heredity.* By DAVID BERRY HART, M.D., F.R.C.P.E. New York: Rebman Company. 1910.

This volume contains, first, a sketch of the work and theories of Darwin, Mendel and their successors; second, an exposition of the author's own theory of the origin and transmission of variations; third, a series of essays or studies in suggested topics, such as "Heredity in Disease," "Evolution and Controversy," "The Handicap of Sex," and "Evolution in Religion." The entire book is exceedingly well written, but the third portion is by far the most entertaining and original, as presenting the shrewd, commonsense reflections of a canny Scotch physician, who is also something of a metaphysician as well. It is particularly interesting to observe the manner in which he explains and justifies Calvinistic predestination as a spiritual counterpart of the law of heredity. The volume is well worth reading for its medical, philosophic and literary merit.

*Principles of Therapeutics.* By A. MANQUAT. Translated by M. SINBAD GABRIEL, M.D. New York and London: D. Appleton & Co. 1910.

This translation of a French work by the national correspondent to the Académie de Médecine aims to present a scientific system of rational therapeutics. Though in his preface the author claims that it is a practical, not a speculative, work, it would seem to the American mind rather theoretic. It contains, however, excellent chapters on the individualisation of therapeutics, and on the resources of non-medicinal agents, such as hygiene, hydrotherapy, climatotherapy, psychotherapy and mechanotherapy. The book should be useful to practitioners who have already mastered the elements of therapeusis, but hardly to beginners in medicine.

*Mind and Health.* The Mental Factor and Suggestion in Treatment with Special Reference to Neurasthenia and Other Common Nervous Disorders. By EDWIN ASH, M.D. Lond. 12mo. Pp. 119. New York: William Wood & Co. London: H. J. Glaisher. 1910.

"A few years ago," says the author, "the very existence of the profound influence which mind exerts over bodily processes in health and disease was absolutely denied by the majority of medical practitioners." Consequently the author devotes the first half of his book to rehearsing cases where the mind has exerted such an influence, citing all the old familiar stories that were probably aged in the days of Aesculapius, and giving various statements to show that mental factors may produce various forms of disease. His arguments would be more convincing if they were more nearly in accordance with the facts, and if he occasionally quoted from some more modern source. The book is utterly commonplace and shows no scientific knowledge.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, FEBRUARY 9, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 809 Paddock Building, 101 Tremont Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.*

*Remittance should be made by money order, draft or registered letter payable to*

W. M. LEONARD,
101 TREMONT STREET, BOSTON, MASS.

## SOME LEGISLATIVE MEASURES NOW PENDING IN MASSACHUSETTS.

THERE are at present pending before the Massachusetts state legislature a number of bills relating to various aspects of the public health. Some of these have already received comment in the columns of the JOURNAL. Some are unimportant, others propose legislation obviously undesirable. Three of the proposed measures seem to deserve consideration at this time.

The first is a bill accompanying a recent recommendation of the Massachusetts Commission for the Blind, and is entitled "An Act Relative to Obtaining Information Concerning the Proper Lighting of Factories and Workshops and Investigating Eye Injuries." It provides, in effect, that the state inspectors of health, while examining the lighting conditions of factories, workshops and other industrial establishments, shall make such investigation as is practicable "concerning the eye and vision in their relation to diseases of occupation, including injuries to the eyes of the employees, and to pathological conditions which are promoted by conditions under which various occupations are carried on." On the basis of such investigations, the State Board of Health is empowered to issue "printed matter containing suggestions to employers and employees for the protection of the eyes of employees," and to direct the adoption of "any mechanical device or other practicable device" by which "the danger of injury may be decreased or prevented." A fine is provided as penalty for failure to comply with any such order, and an annual appropriation is specified for the conduct of the work. The idea embodied in this act seems good, and should be carried out.

The second measure deserving consideration is a bill accompanying the recent "petition of the Massachusetts State Association of Spiritualists for legislation relative to the practice of healing by unregistered physicians." It provides for an amendment to section nine of the chapter of the Revised Laws regulating the practice of medicine in this state so that the provisions of the eight preceding sections of that chapter shall not apply "to persons who treat disease, physical ailments, defects or conditions of any person, or diagnosticate the same with a view to treat by the methods usually employed in the practice of magnetic healing, massage, hypnotism, clairvoyance, mind cure, prayer cure, Christian Science, or methods of healing, if their methods do not, except on advice and in conjunction with a registered physician, involve the practice of surgery, obstetrics or the treating of contagious diseases that are required by law to be quarantined, or the prescribing or administering of drugs, medicines, chemicals and poisons usually known as dangerous agencies, or if they do not hold themselves out as registered according to the preceding sections of this chapter." This blanket clause, though apparently innocent and well safeguarded, in reality opens the door to much freer practice on the part of the persons denominated than is allowed by the present statute. This amendment, therefore, is undesirable and should not be passed.

The third measure to which we wish to refer is a bill accompanying the petition made a year ago "for legislation to provide for the creation of a Bureau of Animal Industry." This proposed act abolishes the present cattle bureau of the State Board of Agriculture and creates a bureau of animal industry of the State Board of Health. This new bureau, to which are transferred the present functions of the cattle bureau, is to be administered by two veterinarians, as chief and assistant chief of bureau, and by such clerks, assistants and agents as the chief shall appoint under the provisions of the Civil Service Commission. Upon it will devolve the making of "orders and regulations relative to the prevention, suppression and extirpation of infectious and contagious diseases of domestic animals, and relative to the inspection, examination, quarantine, care and treatment or destruction of such animals which are affected with or have been exposed to such diseases, and relative to the burial or other disposal of their carcasses and the cleansing and disinfection of districts, buildings or places in which such contagion exists or has existed." Under its jurisdiction also will be the slaughtering and preparation of animals for food, the killing and rendering of horses and the inspection of provisions and animals. Among the diseases coming under its surveillance, according to the intent of this act, are specified "glanders, contagious pleuropneumonia, tuberculosis, Texas fever, foot-and-mouth disease, rinderpest, hog cholera, rabies, anthrax, blackleg, actinomycosis, parasitic diseases and epizootic lymphangitis." The important relation of several of these infections to man, and the close connection between animal industries and human welfare, make it desirable that their supervision and control should be correlated with public sanitation rather than with agriculture, that they should be viewed from an hygienic rather than an economic standpoint. The present bill was brought before the Legislature last year, but did not then receive the serious consideration it deserves. The purport of its provisions is good, and should be incorporated into legislation during the current session of the General Court.

## THE PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM.

SINCE certain physicians have been fined for failing to report cases of ophthalmia neonatorum it is well to recall this warning: "Let physicians report, as the law requires, every case where an infant's eyes 'become swollen and red and show an unnatural discharge.' By reporting every case, regardless of diagnosis, physicians will destroy the superstition which associates ophthalmia neonatorum exclusively with gonorrhea; and by making their reports prompt as well as complete, they will make it possible for boards of health to take quick and efficient action. Only by these means can the physicians, who are responsible, remove the commonwealth's disgrace — its toleration of the blinding of the innocents."

On July 21, 1910, when our editorial columns contained this appeal, perhaps one third of the actual cases of ophthalmia neonatorum were being reported according to law. In the ensuing months, while the proportion of reported cases seems slightly to have increased, the law has still been widely disregarded. And so flagrantly unnecessary do the resulting cases of blindness appear that the State Board of Health, the Boston Board of Health and the Courts have taken action.

The need for their action may be sufficiently shown by two typical cases:

(1) A graduate of Laval, registered as a

physician in this state, attended at a birth, and according to his custom used no preventive. Symptoms of ophthalmia neonatorum were soon brought to his attention. He reported the case. So far, so good. But the local board of health left the child at home in charge of this physician, "helped" by a drunken caretaker. The board of health transferred the child to a hospital, but too late to prevent hopeless blindness.

(2) A graduate of the Harvard Medical School, who is a member of The Massachusetts Medical Society, delivered a child at a suburban hospital. Though he used a preventive at birth, symptoms of ophthalmia neonatorum appeared. After a few days' treatment, he discharged the mother and child, with a mere warning to call in some physician if the eyes did not improve. As he had not reported the case, the excellent local board could not know of the need for action. Nothing was done. And when next the physician saw his patients, the mother was wheeling this blind baby past his door.

The first case suggests the importance of leading local boards to take uniformly effective action for all reported cases; the second shows that obedience by physicians to the law is a *sine qua non* of such action being taken.

To meet the problems suggested by these and by the all too many similar cases, the State Board of Health has adopted this plan: On hearing of any case of ophthalmia neonatorum, whether through reports to boards of health or otherwise, the secretary at once notifies a state health inspector, by telegraph or telephone, to investigate the facts. To insure uniformity and thoroughness, he furnishes each inspector with a rigid *questionnaire*, which the inspector fills out and returns to the secretary. If the inspector's report indicates either neglect or illegality, the secretary notifies both the physician and the local board of health. This plan has already proved stimulating both to physicians and to boards of health.

Meantime the Boston Board of Health has stepped into the forefront of action. It had long investigated reported cases, and where necessary had removed the babies to a hospital for treatment. By persuasive methods it had secured the reporting of a fair proportion of actual cases in 1909. And yet, in spite of the four notices previously sent to all registered physicians in Boston, the board found repeated and dangerous violations of the law. This autumn, accordingly, the chairman began legal action against physicians failing to report. He wisely chose as the first case one not of gonorrheal origin, and one in which blindness had not resulted. The physician in question raised both these points in defense, and he appealed to the Suffolk Superior Court. His conviction is there on record. The Boston Board of Health has since brought into court the three other physicians against whom sufficient evidence has come to light; and out of a total of four cases has secured three convictions. A nurse and another physician have also recently been fined for failure to report cases.

It remains for the Courts to show the importance of this law. Through their clemency, only one delinquent, among three, has paid even the minimum fine. Both legal and medical opinion will support more drastic action.

## THE RESIGNATION OF DR. OWEN COPP.

In the resignation of Dr. Owen Copp as executive officer of the Massachusetts State Board of Insanity, the state loses a public servant it can ill afford to spare. He leaves Boston to accept the position of superintendent of the Pennsylvania Hospital for the Insane at Philadelphia, a private institution chartered in 1751, opened in 1752 as part of the Pennsylvania Hospital for Sick and Injured, and conducted as a separate department from 1841. That this venerable institution should find its new head in Massachusetts is not an unexpected event. The gain to Pennsylvania will undoubtedly prove a distinct loss to Massachusetts, but it is a satisfaction that Dr. Copp is leaving only after the accomplishment of a constructive work, which will greatly simplify the task of his successor. Born in 1858, educated at Dartmouth College and the Harvard Medical School, Dr. Copp began his work with the insane as second assistant physician at the Taunton Insane Hospital in 1885. He became first assistant physician at the same hospital in 1890, and in 1895 undertook the superintendency of the Massachusetts Hospital for Epileptics, a new institution. The establishment of this hospital on a basis of efficiency was due to Dr. Copp's comprehensive grasp of the difficult problem involved, and his administrative capacity. It was therefore not unnatural that he should have been appointed executive officer of the State Board of Insanity when that board needed the services of a man of tried capacity in the development of its plans for a more rational and progressive treatment of the dependents under its jurisdiction. Strongly suggested before, Dr. Copp's exceptional ability was forthwith demonstrated in the conduct of his new and responsible

position. During the period of eleven years which have intervened since his appointment, a comprehensive policy in the care of the insane has been developed, culminating in the establishment of the Psychopathic Hospital now under construction, which will place Massachusetts in the forefront of this field of public service. Dr. Copp's energy, judgment and mastery of detail have contributed largely to this result. He leaves at a time when the plans, with which he has been identified, are likely to be carried to a successful conclusion, no doubt a source of satisfaction to him, as it should be to all who are interested in the public welfare. Unfortunate as it is that this state cannot longer command his services, there is compensation in the fact that his capacity for administrative work of a constructive sort will have still further opportunity for development in the new work which he is about to undertake.

## CENTRALIZATION AND DECENTRALIZATION OF POPULATION.

THE tendency of civilization seems always to have been toward a centralization of population. As commerce, manufactures, learning and wealth develop, the country districts are drained of inhabitants to contribute to the growth of great cities. Recently published census statistics illustrate the truth of this statement in the United States. In Ohio, for example, over 51% of the people live in municipalities with a population over 5,000. During the past decade these communities have shown an aggregate increase of 33⅓% over their population in 1900. During the same period, the rural districts showed a decrease in population of about 17%. There was a net gain of inhabitants, but their distribution was widely altered. Moreover, the larger cities, those with over 25,000 inhabitants, show the greatest proportion of gain. Columbus increased 44.5% in population, Cleveland 46.9%, Hamilton 47.5%, Akron 61.6%, Canton 63.7%, and Youngstown 76.2%.

Another aspect of this centralization of population may be seen by comparing the relative density of population in different states. Published figures from the Census Bureau show the greatest density to be in Rhode Island, where there are 508.5 inhabitants to the square mile. In Massachusetts, which stands second, there are 418.8; in New Jersey, 337.7; in Connecticut, 231.3; in New York, 191.2; and in Pennsylvania, 171. This group of six northeastern states, including three of the five largest cities in the country, constitutes a center of maximum density of population in the United States. At the other end of the list are Arizona, with 1.8 inhabitants to the square mile; Wyoming, with 1.5; and Nevada, with 0.7.

A certain amount of centralization is, of course, inevitable and desirable for the highest advancement of humanity. Man is naturally gregarious, and to his association in communities is due his progress. The only question is what limit shall be put on the size of these communities. In America there seems already to be a slight spontaneous tendency to self-limitation by the growth of suburban towns; but though this ameliorates the condition of certain classes, it does not affect the worst evils of city life. Deliberate decentralization, by improvement of peripheral transit and reduction in cost of living in the country, may become the means by which these evils may be most efficiently combated in the future.

## THE OPTOMETRY BILL AGAIN.

EVERY year attempts are made before our legislature to pass laws harmful to medical standards in Massachusetts, and the present year is no exception. Although the optometry bill was overwhelmingly defeated last year, the opticians are again before the legislature with a similar bill. Their arguments are the same as before, and they are particularly active in sending to representatives and senators plausible campaign leaflets, distributed from headquarters in New York. They are also sending appeals to doctors asking them to advocate the cause. As in other years, the opticians or optometrists ask for a board of registration in what they call optometry, which shall give them a state license to fit glasses, so that in future no one but those thus licensed shall be allowed to fit lenses, except, of course, medical men. They ask protection for the public from the traveling fakir who sells glasses, and also that their optometry board shall be made up of men from their own ranks, who shall be judges of the nature of the examination and of the standard in marking.

That this system of licensing opticians under the new name of optometrists means licensing a sort of irregular medical practitioner is clearly shown by the experience of those states which have unwisely adopted this optometry legislation.

Without exception, the optometry examinations in these states contain questions on anatomy, physiology and pathology of the eye. Optometry journals are full of crude papers on medical subjects relating to the eyes, and the optometrists openly claim to be judges of the complicated reflex relations of the eye and to be able to tell the difference between the headache of refractive troubles and the headaches due to other causes, and further, to be able in all cases to do refraction without the use of a mydriatic or other drug.

The fight against the optometry bill was led successfully last year by The Massachusetts Medical Society. Medical men should be on their guard against incautiously lending their sanction in any way to this legislation.

## PROSECUTIONS UNDER THE PURE FOOD LAW IN MASSACHUSETTS.

Before the United States district court in Boston last week, a certain manufacturing company was fined $75 for violation of the pure food law in misbranding an Egyptian deodorizer, an orange extract and a vanilla extract. Under the same law, the United States Deputy Marshal seized last week in this city one hundred large cans of frozen eggs, shipped from Chicago and chiefly consigned to local bakers.

The number and extent of violations of the pure food law and drug laws in Massachusetts may be realized from the recently published report of the State Board of Health relative to its prosecutions and expenditures for inspection in the year ended Nov. 30, 1910. During this time 7,805 samples of food and drugs were examined, of which 1,527 were found not conforming to the statutes. Of these, 1,043 were samples of milk below standard, 332 were adulterated foods other than milk, and 152 were adulterated drugs. As a result of these examinations, 257 prosecutions were made, of which 244 resulted in conviction. Among the offenses for which conviction was obtained were the sale of milk not of good standard quality, of adulterated cream, of unmarked renovated butter, of oleomargarine as butter, of hamburg steak adulterated with sulphurous acid, of adulterated sausages and sausage meat, of lard and olive-oil adulterated with cottonseed oil, of maple sugar adulterated with cane sugar, of decomposed peanuts, of rolled wheat containing dead insects, of distilled and artificially colored vinegar, of diluted alcohol, and of camphor liniment, spirit of anise, tincture of ginger and tincture of iodine deficient in strength. This catalogue of offenses serves to illustrate the persistent obliquity of mankind and the necessity of such continued zeal as that of the Board of Health in the detection and prosecution of violators of law.

## MEDICAL NOTES.

New Trustees of the Carnegie Institution of Washington. — Dr. H. P. Walcott, of Boston; Dr. Simon Flexner, of New York; and Mr. Robert I. Brookings, of St. Louis, have been elected trustees of the Carnegie Institution of Washington.

Solidification of Oxygen. — Report from London states that Sir James Dewar has recently announced to the Royal Institution that he has succeeded in solidifying oxygen by means of the cold generated by its own evaporation from the liquid state. It was Professor Dewar who first succeeded in producing liquid air.

Further Seizures of Opium and Arrest of Smugglers. — It is reported from Honolulu that on Jan. 28 $10,000 worth of opium was seized aboard the Pacific liner *Hong Kong* on her arrival in that port from the Orient. A steward and three Chinese sailors were arrested.

At San Francisco, on Jan. 30, a watchman at the Pacific Mail docks was arrested on a charge of having concealed in his room thirty tins of smuggled opium. Some of the drug was found in his pockets at the time of his arrest, and he is said to have acknowledged having acted as agent for several persons concerned with the smuggling of opium into this country.

Three Centenarians. — Miss Victoria Kuschura, who died last week at Duluth, Minn., is said to have been born in 1804, in Poland.

In the issue of the Journal for Jan. 26, we chronicled the persistent vigor and laudable energy of Mr. Daniel Short, of Cambridge, Mass., who, at the reputed age of over one hundred years, continued his occupation as driver of a dump-cart in that city. Mr. Short died last week at the Cambridge Relief Hospital, as a result of injuries received by falling from his cart. He is said to have been born on Nov. 11, 1810, in County Tyrone, Ireland, and to have migrated to the United States in 1849.

Daniel Davis, of Royalston, near Athol, Mass, is said to have been born on Feb. 4, 1809.

New Water Supply at Vienna. — Report from the United States Cousul General at Vienna

describes the opening last December of a new aqueduct, which has been under construction for the past twelve years, to furnish a new and adequate water supply to the growing city. This supply is derived from the Salza River, a branch of the Ems, which runs along the base of the Hochschwab Alp, through a district with few inhabitants and no industrial establishments or factories, and is, therefore, practically free from liability to pollution. The aqueduct is 120 miles long and delivers 200,000 cubic meters of water a day at a temperature of 36° F. The total cost of the aqueduct will be equivalent to over $18,000,000.

MURDER BY BACTERIAL TOXINS. — The daily press has lately contained somewhat lurid but nevertheless interesting accounts of the trial at St. Petersburg of a Dr. Pantchenko, a Russian physician charged with having murdered about forty persons by inoculating them with the toxins of diphtheria or cholera. His alleged method of procedure was to obtain these toxins by filtering virulent cultures of the organisms and then injecting a lethal dose of the fluid subcutaneously under the pretext of giving some medicine. The victims died with symptoms of general toxemia, but at autopsy no evidence of infection could be found. Whether or no there be any truth in these allegations, the story suggests another of the possible opportunities for crime which the special knowledge and privileges of the profession place in the hands of physicians.

PRUSSIAN POPULATION AND GERMAN BIRTH-RATE. — Census statistics, published on Feb. 4, in Berlin, show that the population of Prussia has increased from 34,472,509, in 1900, to 40,157,573, in 1910. Despite this gratifying increase, however, it appears that the birth-rate in Germany is already on the decline. In 1875 it was 42 per 1,000; during the decade ending in 1890 it averaged 36 per 1,000; and in 1910 it was 33 per 1,000. There is still a considerable margin, however, between it and the death-rate; and though these figures may represent, as handwriting on the wall, an impending decline of Teutonic racial fecundity and vitality, it should be some time before Germany finds itself in the same plight as France or the native Yankees of New England.

TAXATION OF BACHELORS IN ENGLAND. — An item in the Dundee (Scotland) *Advertiser* contains some interesting information in regard to the taxation of bachelors. In 1695 a minimum tax of a shilling a year was levied in England on every bachelor over twenty-five years of age and on every childless widower of five years' standing, and this tax continued in force until 1706. Its purpose, however, was not to check race suicide, which had not then begun to worry the world, but to provide the royal exchequer with funds for carrying on the wars with France. It should be added that at the same time there was also a tax on births, marriages and burials, so that the net result should have been less to encourage matrimony than to drive able-bodied men into the army, where they became exempt from taxation.

THE PLAGUE EPIDEMIC IN CHINA. — The epidemic of bubonic plague appears to be still active in Manchuria and China. Its victims are chiefly natives, though a certain number of Europeans have already perished of the disease, especially among the physicians and missionaries. On Feb. 1 it was reported from Pekin that 20 deaths from plague had occurred in the Chinese hospital at Tientsin, and it is estimated that probably 500 deaths from the disease are occurring daily in the entire infected district. Report from Berlin on Feb. 3 stated that the plague had broken out along the course of the Shantung Railroad, a German line extending from the seaport of Tsintau to Tsinan-Fu, 247 miles inland. This road has now been closed to second- and third-class traffic. Apparently the authorities in charge are doing the best that under the circumstances can be done to check the spread of the pestilence, but under prevailing oriental conditions, and in face of an infection of exceptional virulence, their efforts are not likely to be successful before a considerably greater extension and mortality have occurred.

## BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 7, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 49, scarlatina 42, typhoid fever 5, measles 110, smallpox 0, tuberculosis 75.

The death-rate of the reported deaths for the week ending Feb. 7, 1911, was 17.71.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Feb. 4, 1911, was 220, against 218 the corresponding week of last year, showing an increase of 2 deaths, and making the death-rate for the week, 16.65. Of this number 122 were males and 98 were females; 210 were white and 10 colored; 134 were born in

the United States, 81 in foreign countries and 5 unknown; 48 were of American parentage, 142 of foreign parentage and 30 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 49 cases and 2 deaths; scarlatina, 44 cases and 5 deaths; typhoid fever, 4 cases and 0 deaths; measles, 133 cases and 1 death; tuberculosis, 52 cases and 17 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 28, whooping cough 4, heart disease 36, bronchitis 5. There were 18 deaths from violent causes. The number of children who died under one year was 37; the number under five years, 55. The number of persons who died over sixty years of age was 62. The deaths in public institutions were 83.

Life and Scientific Works of Alexander Agassiz. — A memorial address on this subject is to be delivered by Sir John Murray in Sanders Theatre, Harvard University, on Tuesday evening, Feb. 14.

William Belden Noble Lecturer. — Wilfred T. Grenfell, M.R.C.S., L.R.C.P., M.D. (Hon.), LL.D., has been appointed lecturer on the William Belden Noble Foundation for 1911–12 at Harvard University.

Appointment of Dr. Dyer. — The appointment was announced last week of Dr. Robert E. Dyer, of South Boston, as veterinarian to assist Dr. Alexander Burr, of the Bureau of Dairy Inspection of the Boston Health Department.

Fines for Failure to Report Ophthalmia. — A physician and a nurse were fined $20 and $10 respectively last week before the Boston Municipal Court for failure to report a case of ophthalmia neonatorum upon which they were in attendance.

New Building of Massachusetts Homœopathic Hospital. — On the afternoon of Feb. 4, at the Massachusetts Homœopathic Hospital, the cornerstone of the new Robert Dawson Evans Memorial Building for Clinical Research and Preventive Medicine was laid with appropriate ceremonies.

A Living Centenarian. — Mrs. Calvin Brigham, of Worcester, Mass., celebrated, last week, the supposed centennial anniversary of her birth. Her maiden name was Susan S. Wetherbee, and she is said to have been born on Feb. 3, 1811, at Acton, Mass. In 1830 she came to Worcester, where she subsequently married and has lived ever since. She has been a widow for the past forty-five years. Her health was excellent until two months ago.

Needs of the Massachusetts School for Feeble-Minded. — At a hearing last week before the committee of the state legislature on public charitable institutions, Dr. Walter E. Fernald, of the Massachusetts School for Feeble-Minded, appeared in support of his request of an addition of $25,000 for that institution, $15,000 for an addition to the Nurses' Home and $10,000 for a new building for adult male patients.

Associate Membership in Boston Medical Library. — Recently adopted changes in the by-laws of the Boston Medical Library establish an associate membership, to which are eligible properly qualified physicians living outside Boston. Physicians resident in Boston may be associates only during the first five years after receiving their medical degree. It is provided that "associates shall have the same privileges as Fellows, except that they shall have no vote. They shall pay half the dues of Fellows."

Diphtheria in Fitchburg. — During the current winter diphtheria has been more than usually prevalent among the public schoolchildren of Fitchburg, Mass. Up to the end of January, 440 cases of the disease had been reported in that city, and since that time there have been about 260 more. Only one death has thus far occurred in this epidemic. The schools have not been closed, but an extensive series of cultures has been taken among the pupils and a number of carriers found. On account of the recent rapid increase in the incidence of the infection, it is purposed to pursue more rigorous quarantine measures in the effort to check the spread of the disease immediately.

Nitrous Oxide and Oxygen Anesthesia. — At the Harvard Dental School, on Jan. 31, Dr. Charles K. Teter, of Cleveland, Ohio, made an address on "The Uses for Nitrous Oxide and Oxygen in Dental Surgery," and subsequently gave several practical demonstrations of this method of anesthesia. On Feb. 1, in the amphitheater of the Massachusetts General Hospital, he made similar demonstration of its applicability for the purposes of general surgery. Dr. Teter is an expert in this subject, and his recent visit to Boston has afforded the profession of this city valuable opportunity to see and study his methods. Those who were unable to do so may find them outlined in his paper on "Nitrous Oxide and

Oxygen," read before the meeting of the Northwestern Dental Association in Boston last October. The combined use of nitrous oxide and oxygen seems to afford a safe and valuable means of general anesthesia in certain cases in which the use of the commoner anesthetic agents is contraindicated. It deserves study and judicious employment both in dental and in general surgery.

### NEW YORK.

MT. SINAI HOSPITAL ASSOCIATION. — The fifty-eighth annual meeting of the Mount Sinai Hospital Association was held on Jan. 22. The receipts of the hospital for the year were $426,138, or $12,228 more than the expenditures. Bequests amounting to $73,762 had been received, which reduced the deficit of the institution to $10,228.

EPIDEMIC OF SCARLET FEVER. — An epidemic of scarlet fever is prevailing at Ossining and other places along the Hudson River, and on Jan. 27, Dr. Robert T. Irvine, the health officer, and other officials of the town of Ossining held a conference with representatives of the State Department of Health in regard to the situation.

MEMORIAL MEETING FOR DRS. ELIZABETH AND EMILY BLACKWELL. — A memorial meeting in honor of the late Drs. Elizabeth and Emily Blackwell, the pioneer women in medicine in this country, was held at the New York Academy of Medicine, and among the speakers were Drs. William H. Welch, of Johns Hopkins University; Stephen Smith, and Abraham Jacobi.

SURGICAL CLINIC FOR ANIMALS. — A surgical clinic for animals has been opened at the Cornell Medical College, under the direction of Dr. F. W. Gwyn, professor of operative and clinical surgery, with Dr. Thomas G. Sherwood veterinarian in charge. This clinic is designed to supplement that of the New York League for Animals, to which Mrs. Russell Sage recently contributed $1,500, which, it is stated, cares only for medical cases. Aside from the usefulness of the clinic to the poor, Dr. Gwyn believes that its work will prove of decided value to the Cornell students.

MEMORIAL TO DR. MACDONALD. — On Feb. 3 Governor Dix was elected president of an association which has been organized to raise funds for a memorial in honor of Dr. Willis G. MacDonald, the distinguished Albany surgeon, who died recently. The association met at the State Capitol, and the hope was expressed that $100,000 might be raised for a laboratory in connection with the Albany Medical College, in which Dr. MacDonald was professor of surgery.

THE PRICE OF A POUND OF FLESH. — Municipal Court Justice Davies was recently called upon to decide, as in the case of "The Merchant of Venice," upon the commercial value of a pound of flesh. A certain Harlem practitioner had brought suit for the collection of a bill, one item of which was "$14 for the removal of fourteen pounds of excess avoirdupois tissue." After the hearing of the case the magistrate decided that the rate of $1 a pound was fair. As some of the patient's surplus flesh had come back, however, this was considered a complicating circumstance, and accordingly the doctor was asked if it was his custom to grant rebates if the fat came back. "In that case," the Court went on to say, "I will allow a leeway of two pounds, and award you a decision of $12, which is your normal rate with a margin for debatable differences."

SCHOOL INSTRUCTION IN SEX HYGIENE. — The fifth congress of the American School Hygiene Association was held at the New York Academy of Medicine on Feb. 1, 2 and 3. Dr. Luther H. Gulick, of New York, presided, and among the features was an address on "School Instruction in Sex Hygiene" contributed by Charles W. Eliot, president emeritus of Harvard University.

BETH ISRAEL HOSPITAL. — The annual meeting of the Beth Israel Hospital was held on Jan. 29. During the past year 2,114 patients were treated, and of these, 1,149 were born in Russia, 527 in the United States, and 201 in Austria-Hungary and Galicia. Seven other nationalities were also represented. The total receipts for the year were $122,965, and the total expenses $123,026. It was announced that the site for a new building had not been selected, but it was hoped that this would shortly be done. The subscriptions to the building fund already amount to $188,609, of which $74,109 has been actually paid.

PURE MILK FOR INFANTS. MEASLES HOSPITAL. — In an address at the New York Academy of Medicine, on Jan. 27, on "Some Features of the Work of the Department of Health," Commissioner Lederle announced that the department, with the $40,000 recently appropriated for the purpose by the Board of Estimate and Apportionment, would soon open fifteen stations for the dispensing of pure milk for infants. This new departure, he said, had been decided upon when Nathan Strauss thought of giving up the milk depots which he had been maintaining. The latter were now to be continued, but the new

stations were not designed to compete with those of Mr. Strauss, and would be located in different neighborhoods. The health department would not dispense free milk, but sell it at as low a price as possible. He also announced that plans had been made for the erection of a hospital for measles patients at the foot of East Sixteenth Street, at a cost of $200,000; that a dormitory for employees of the city hospitals, to cost $85,000, would be built adjoining this, and that an extension, costing $100,000, would be made to the tuberculosis hospital on North Brother Island.

Appeal from Verdict for Malicious Prosecution. — The County Medical Society has won its appeal to the Appellate Division of the New York Supreme Court from a verdict of $7,500 for malicious prosecution awarded by a supreme court jury to one Paul Schmidt. Schmidt and his associate, Carolus Conradus, were prosecuted by the society for illegally practicing medicine, in 1909 and were discharged in the Court of Special Sessions. The Appellate Division holds unanimously that the society was justified in bringing Schmidt to trial, and in delivering the opinion Justice McLaughlin says: "I do not see how any person of ordinary intelligence would not have probable cause for believing that the plaintiff [Schmidt] was engaged in the practice of medicine. . . . These facts, being uncontradicted and unexplained, justified the defendant [the medical society] in doing what it did. The trial court should have so held and dismissed the complaint at the close of the plaintiff's case, and, having failed to do that, should have directed a verdict for the defendant at the conclusion of the whole case."

Increase of Suicides and Homicides. — A marked increase in the city in the number of homicides and suicides by shooting has led officials of the coroner's office to start a movement which they hope will lead to new legislation restricting the sale and carrying of firearms, especially revolvers. Based upon a study of conditions concerning homicides and suicides for the last thirteen years, a list of recommendations to the legislature has been drawn up by George Petit Le Brun, one of the coroner's clerks. The annual report of the coroner's office, just made public, also urges legislative action. "The increase of homicide by shooting," it says, "indicates the urgent necessity of the proper authorities taking some measures for the regulation of the indiscriminate sale and carrying of firearms." The report shows that in the borough of Manhattan the total number of homicides in 1910 was 185, an increase of 75 over those of 1909. The total number of deaths from all causes reported to the coroners in 1910 was 5,408, an increase of 186 over the previous year, and of this total, 2,483 were of a violent character, showing an average of more than 6 violent deaths for each day of the year. The total number of suicides was 485, an increase of only 2 over 1909. Gas was the principal agent of death employed,—in 142 cases,—but the number of suicides by shooting was nearly as large, 133; while there were but 28 deaths from poisoning. In 1900 no less than 185 suicidal deaths were from carbolic acid, but within the last few years, on account of the difficulty of procuring poisons, in consequence of the stricter regulations regarding their sale, there has been a marked decrease in suicide by poison.

Commission to Determine Robin's Sanity. — Judge Swann of the General Sessions Court recently appointed Drs. Charles L. Dana and Pearce Bailey as a commission to inquire into the mental condition of Joseph G. Robin, who is under indictment for grand larceny in connection with the closing of the Northern and the Washington savings banks. The method adopted in this case is new, the practice previously employed having been to have a commission consisting of a physician, a lawyer and a layman act with a sheriff's jury. Robin's examination was under Section 836 of the new Penal Law, which provides that two physicians shall be appointed by the court to examine a person accused of crime whose sanity is in question, and then advise the court and jury. When the case came up in court on Jan. 31, the prisoner was declared insane by Drs. Dana and Bailey; but, notwithstanding their testimony and that of four other well-known alienists to this effect, the jury rendered a verdict that he was sane, and Judge Swann expressed himself as satisfied with their decision. The other alienists were Drs. Allan McLane Hamilton and Smith Ely Jelliffe, of New York; and Dr. William A. White, of Washington, who had examined Robin for the district attorney; and Dr. Austin Flint, who had examined him for the defense. There was no dissenting opinion as to his insanity among these experts, and, as a result of this ignoring of their testimony, the Section on Neurology and Psychiatry of the New York Academy of Medicine, when it met for its monthly session on Feb. 1, resolved itself into an indignation meeting to protest against the court proceedings. After considerable discussion it was voted

that the chairman of the section, Dr. Schlapp, should appoint a committee to formulate some plan of action.

INVESTIGATION OF POLIOMYELITIS. — The Rochester Academy of Medicine has adopted resolutions asking the State Department of Health to make a field investigation of epidemic poliomyelitis and petitioning the legislature to make an appropriation for the suppression of the disease, as has been done by the legislatures of Massachusetts, Pennsylvania and other states. In the resolutions it is stated that "the attention of the State Commissioner of Health is called to the facts that poliomyelitis (infantile paralysis) is prevalent in Canada along the Niagara frontier, that there is constant intercourse during the summer between Canada and New York state, that many cases in Buffalo in 1910 were probably infected in Canada, and that interchange of information and an agreement as to quarantine regarding poliomyelitis between Ontario and New York state would be most desirable. It is obvious that the disease can only be watched and controlled by a strong central authority, the State Health Commissioner, and that he should have a staff of skilled specialists at his disposal." In New York City sixteen cases of poliomyelitis have been reported to the Board of Health since November last, when the disease was declared communicable and was included in that section of the Sanitary Code which requires physicians to report cases. Of late, the Division of Communicable Diseases of the Health Department has devoted special attention to the clinical history and nature of this disease, and on Feb. 3 Commissioner Lederle made public a report on the subject. In this a description of the symptoms is given; after which it is stated that "the period of incubation varies widely, from two to thirty days. The average appears to be seven to ten days. The so-called abortive cases may act as carriers, and there are also many authentic cases on record in which the disease was in all probability carried by a third person. The duration of the period of infectivity is unknown, which leaves the question of isolation and quarantine unsettled."

20. NILES, G. M. *Optimistic Therapeutics.*

1. Matas and Allen have found experimentally that unless trauma be sufficiently marked to crush the tissues throughout the entire thickness of the vessel wall, no changes will be noted either in the endothelial lining or in the inner layers of the muscular coat in vessels which have been clamped for seventy-two hours or less. Longer pressure causes changes, the degree of which is measured by the length of pressure.

2. Chalfant ascribes the cause of uterine hemorrhage in the arteriosclerotic type of cases to some loss of functional power of the uterine muscle, for proper uterine contraction is essential to the control of uterine bleeding. There is no pathological condition present in this type of case that is not found in others not giving any history of hemorrhage, with the possible exception of increase in number and size of the vessels. The loss of functional power is due probably to the development of fibrous and elastic tissue from subinvolution.

11. Graham reports a case of idiosyncracy to aspirin in which one 5-gr. dose produced almost immediate symptoms, with edema of the mucous membranes of the eyes, nose, mouth and marked shock followed by a long period of somnolence.

18. Werelius is advising and trying out the tubal implantation of the ureters in females when it is advisable to extirpate the bladder or for extrophy of that viscus.

6. CULLEN, T. S. *Carcinoma of the Right Fallopian Tube Readily Palpable through the Abdomen.*
7. BRÖDEL, M. *In Memoriam. August Horn.*

1. Brown discusses urinary hyperacidity and its relation, which he believes to be a very definite one, to certain so-called idiopathic cases of neuritis, neuralgia and myalgia. The hyperacidity he explains as due to some metabolic change. In these cases a simple dietary, copious water drinking and the administration of alkalies to reduce the acidity of the urine to normal has been followed by marked relief.

4. Austrian presents an elaborate and interesting study

of the viscosity of the blood in health and in disease. In health it is greater in men than in women; viscosity depends on the number of red corpuscles, the hemoglobin content and the gaseous richness; it is not influenced by diets used over short periods of time. The viscosity of normal plasma is 1.7–2.0, average 1.86. In disease it varies greatly. In anemias, primary or secondary, it is reduced and with regeneration of blood becomes normal. In leukemia there is hypoviscosity of the blood and hyperviscosity of the plasma. Both are increased in polycythemia. In cardiac disease there is no change in relation, both are increased. In icterus there is generally increased viscosity, as is the case in pneumonia. In typhoid fever the viscosity varies with the anemia. The Hess viscometer was used in every case. The figures show the relation of the viscosity of blood to water. [J. B. H.]

11. Grünbaum, O. *The Technic of Intravenous Injection of Ehrlich-Hata Preparation "606."*
12. Hericourt, J. *Raw Meat and Raw Meat Juice in the Treatment of Consumptive Diseases (Zonotherapy).*

2. Shaw presents tables and statistics to show that pulmonary tuberculosis is on the average a far more chronic disease than is generally considered to be the case. Many such chronic cases, as long as they are carefully instructed in methods by which they can avoid infecting others and maintain their own health, can go to work and discharge their duties in life as any other person. Instead of putting three to four years as the average duration of the disease, he would place it at seven to eight years or more.

5. Fisher calls attention to a diastolic murmur which is occasionally heard at the apex of the heart and is often mistaken for mitral stenosis; he believes it to be a purely functional murmur. Such a murmur is rarely constant, but comes and goes.

7. Yeo records another case of advanced pulmonary tuberculosis much benefited by wearing a mask by means of which she inhaled constantly an antiseptic vapor. The patient was in a sanatorium while undergoing treatment. He states that "he knows of" many other cases benefited by this treatment. (*Cf.* editorial note. Despite this case and other isolated cases, the inhalation treatment of pulmonary tuberculosis cannot yet be accepted as of much value. — J. B. H.) [J. B. H.]

### British Medical Journal.

#### Jan. 7, 1911.

1. *Bennett, W. *The Treatment of Venous Thrombosis Mainly from the Surgical Aspect.*
2. *Poynton, F. J. *Some of the Rarer Occurrences in the Rheumatism of Childhood.*
3. *Fenwick, E. H. *Clinical Lectures on Kidney Pain.*

5. Little, E. G. *The Treatment of Rodent Ulcer.*
6. Lane, W. A. *Excision of a Cancerous Segment of the Esophagus. Restoration of the Esophagus by Means of Skin Flap.*

1. Bennett, in an article on the surgical treatment of venous thrombosis, describes the operation itself both in simple thrombosis and in thrombosis with embolism and some points relating to the general treatment of thrombosis. He briefly discusses varicosity consequent on thrombosis and its treatment.

2. Poynton, in a paper on rheumatism in childhood, describes the occurrence of rashes, erythema nodosum, venous thrombosis, tachycardia, mastitis and epistaxis.

3. Fenwick, in a clinical lecture on kidney pain, starts with two aphorisms: (1) the commonest structural change accompanying kidney pain is dilation of the renal pelvis; (2) the commonest cause of kidney pain is dilation of the renal pelvis. He discusses (1) the value as a symptom in kidney diseases (excluding diabetes and certain poisons) of excessive thirst. (2) The posture of the patient in sleep; in acute inflammations the patient *cannot* sleep on the affected side. (3) Intermittent diuresis, which in his opinion always marks some dilation of the pelvis. This he believes explains many cases of so-called diabetes insipidus. He concludes by discussing the operative points of dilated renal pelvis.

4. Calwell, in an address on the prevention of heart disease, among other things describes a much-neglected factor in causing a chronic weak heart — hard physical exercise when the patient is out of training either from previous lack of exercise or during or after slight ailments, such as common colds, grip, etc. (In the reviewer's opinion this is an important and much-neglected source of trouble among young men, recent college graduates who are apt to consider strenuous physical exercise a cure for all ills. — J. B. H.) [J. B. H.]

15. MÜLLER, F. *Talk on the Opening of the New Policlinic Building in Munich.*

1. Ehrlich reviews the results thus far obtained in the treatment of syphilis with "606." He says it is still too soon to affirm that lasting cures can be effected with a single dose of 0.4 to 0.5 gm., but he believes, nevertheless, that complete cures have been effected. Among the evidence for this he cites cases in which, after a prompt cure of the original chancre, other chancres appeared in other places. These were attributed to reinfection. It seems that most of the deaths following the use of "606" might have been avoided if Ehrlich's advice had been more strictly followed. He emphasizes the danger of giving it when the heart is weak, and in cachectic states not due to syphilis. He thinks that it may sometimes be wise to repeat the dose and to use mercury in the interval. The neutral emulsion has proved less satisfactory than the solution, and the intravenous method has the advantage of avoiding local lesions and difficulties of absorption.

2. The writers say that in the two years since digipuratum was first used it has proved itself the best preparation of digitalis. The advantages are that it has a known strength, that it disturbes the digestion less than any other preparation of digitalis and that it keeps well. [G. C. S.]

9. HOFFMANN. *Progress in the Field of Tropical Diseases.*
10. HILDEBRAND, O. *Life of Franz König.*

5. The author reviews the results obtained by other observers. He reports two cases of his own in which this treatment was followed. In neither case could there be found a trace of arsenic in the milk. The temporary improvement seemed due to the toxins in the milk due to the destruction of the organisms in the mother. Both of these cases finally resulted fatally and came to autopsy. The first case showed no specific organisms; the second case, however, did. [J. L. H.]

5. Sergent, E., and Sergent, E. *Epidemiologic and Prophylactic Studies on Malaria.*

1. Landsteiner and Levaditi have been carrying on experiments with poliomyelitis virus along similar lines to those followed by Flexner and Lewis in New York, by Leiner and Wiesner in Weichselbaum's laboratory at Vienna, and by Roemer at Marburg. In this article they describe the results of their experiments and compare them with other authors' results. They describe first the clinical course of this disease when transmitted by inoculation into monkeys. There are two chief types, the ascending and the superior, dependent upon what part of the nervous system is attacked. On histologic study the lesions are found similar to those seen in man. No Negri bodies, similar to those found in rabies, were observed. Animals sacrificed during the incubation period showed no lesions. Attempts at repair are seen after the acute stage passes off. The virus disappears from the central nervous system within a few days after the acute period. Degenerative lesions occur in the muscles.

The virus is filterable through the very finest filters and is more readily preserved than the virus of rabies. *In vitro* menthol, potassium permanganate and hydrogen peroxide destroy the virus. Injections into the spinal or cranial cavity and intraperitoneally are the most successful. Some success has been had with intravenous, subcutaneous and intraneural injections. Proof seems to exist that the virus travels along the nerves to the central nervous system. It is difficult to infect by ingestion, but possible especially on injured mucous membranes. Infection by the respiratory tract is possible, especially after injury to the mucous membrane.

The best material for infecting purposes is the macerated nerve tissue. Cerebrospinal fluid is not satisfactory. Some have had success from nasal secretions. Other body fluids and organs have given negative results as a rule. The authors have never seen or read of any evidence of contagiousness among monkeys. Some immunity is established by a light attack. Vaccination by infectious material of diminished virulence offers protection to otherwise fatal doses. Serum of monkeys in an acute attack will destroy the power of the virus *in vitro* but does not help in the living monkey when injected during the incubation period, nor do any of the drugs tried, such as arsenic. [C. F., Jr.]

Bullettino delle Scienze Mediche.

November, 1910.

1. *Melli, A. *The Resistance of Corpuscles in States of Experimental Acidosis Produced by Hydrochloric Acid.*

1. This entire number consists of an elaborate experimental study by Melli of the resistance of red blood corpuscles in acidosis. After considering the signs of their resistance in various morbid processes and in physiologic conditions, he describes the methods employed in his research and reports his experiments and results. He concludes that under normal conditions the minimal resistance of canine red blood corpuscles to chlorine solutions is from 46 to 56%, the average from 36 to 44%. Both these diminish in acid intoxications. Acute acidosis may be recovered from, but chronic acidosis conduces to inevitable death. States of acidosis, whether acute or chronic, accelerate and exaggerate the destructive processes of the red corpuscles. The author believes that these findings have an important clinical bearing in such conditions as gout and scorbutus. [R. M. G.]

## Obituaries.

### JAMES KERR, M.D.

Dr. James Kerr, of Washington, D. C., who died in Warrenton, Va., on Feb. 2, was born on Dec. 14, 1848, at Portstewart, County Derry, Ireland. He graduated from the Royal University, Dublin, in 1870, and in the same year received the degrees of M.D. and M.Ch. from Queen's College, Belfast. Coming immediately to Canada, Dr. Kerr served until 1873 as surgeon of the Royal Canadian Mail Service. He then served for a year as surgeon for a royal transport on the Gold Coast Expedition. In 1876 he was married at Brantford, Ont. In 1882 he was appointed chief surgeon of the Canadian Pacific Railway, and in 1883 became professor of surgery and president of the Manitoba Medical College. In 1885 he served as surgeon in the Canadian militia. In 1891 he became professor of surgery at Georgetown Medical College, Washington, D. C., and since then had lived and practiced in that city. He was a member of the Washington Academy of Sciences.

### FREDERICK COGGESHALL, M.D.

Dr. Frederick Coggeshall, who died in Boston on Feb. 1, was born on Jan. 8, 1861, in New York City. He received the degree of A.B. from Harvard in 1886, and that of M.D. in 1892. Immediately after graduation he began the practice of medicine in Boston, and in 1893 was appointed physician for nervous diseases at the Boston Dispensary, a position which he held until shortly before his death. He had also served as physician to the Boston Floating Hospital and as pathologist at the Carney Hospital. He was a member of the American Medical Association, of the American Academy of Medicine, a fellow of The Massachusetts Medical Society, a member of the Boston Medical Library and of the Boston Society for Medical Improvemwnt. He is survived by his widow and by one son.

## Miscellany.

### THE MASSACHUSETTS MEDICAL SOCIETY.

A stated meeting of the Council was held in John Ware Hall, Boston Medical Library, Feb. 1, 1911, at 12 o'clock noon, the President, Dr. George B. Shattuck, in the chair and eighty-one councillors present.

The record of the last meeting was read and accepted.

Dr. O. F. Wadsworth, for the Committee on

Publications, announced that Dr. David L. Edsall, of Philadelphia, would deliver the Shattuck Lecture in 1912.

Dr. Goss reported for the Committee on Membership and Finance, and in accordance with the recommendations of this committee it was voted that the resignation of two members be accepted; also that seven members be placed on the retired list.

The Secretary read the reports of the committees appointed to consider petitions of two members for reinstatement, and it was voted to reinstate them.

Committees were appointed to consider the petitions of three members for reinstatment.

Dr. Rogers, for the Committee on Medical Diplomas, presented a revised list of the medical schools and colleges of the United States and Canada for the purposes set forth in By-Law 1, and the list was adopted by unanimous vote.

The Committee of Arrangements reported, through Dr. G. H. Francis, "that in the opinion of the committee it would not be desirable to hold the annual meeting of The Massachusetts Medical Society in Worcester in 1911." Voted to accept the report.

Dr. E. W. Taylor, for the committee appointed at the last meeting to consider the method of appointment of the officers of the sections, reported as follows:

*Moved:* That the officers of the medical and surgical sections for the annual meeting of The Massachusetts Medical Society be elected as follows:

On the organization of the section meetings the chairman of each section shall appoint a nominating committee of three who shall present to that section nominations for chairman and secretary for the ensuing year, these nominations to be voted upon the same day.

Voted to accept the report.

Upon the nomination of the President the following delegates were appointed:

To the meetings of the American Medical Association for the ensuing two years:

F. H. Thompson, Fitchburg; F. G. Wheatley, North Abington; Hugh Cabot, Boston.

Alternates:

I. S. F. Dodd, Pittsfield; A. Greenwood, Waltham; F. T. Murphy, Boston.

To the annual meetings of the following state societies:

Maine Medical Association: G. K. Blair, Salem; H. W. Manahan, Lawrence.

New Hampshire Medical Society: G. Z. Goodell, Salem; O. P. Porter, Lowell.

Rhode Island Medical Society: A. Greenwood, Waltham; N. S. Hunting, Quincy.

Connecticut State Medical Society: E. A. Bates, Springfield; S. B. Woodward, Worcester.

To the Council on Medical Education and meeting of Association of American Medical Colleges, Chicago, Feb. 27 to March 1: H. C. Ernst, Boston. Alternate: H. D. Arnold, Boston.

Upon the nomination of the President, Dr. C. C. Sheldon, of Lynn, and Dr. E. Flagg, of Boston, were appointed a committee to audit the Treasurer's accounts, and Dr. E. W. Taylor, of Boston, was appointed a member of the Committee on Publications, to fill a vacancy.

Dr. H. D. Arnold made a motion:

That hereafter those members of The Massachusetts Medical Society who attend the meetings of the House of Delegates of the American Medical Association as the authorized representatives of The Massachusetts Medical Society may be reimbursed by the Treasurer of said society for their transportation and ordinary sleeping accommodations while traveling to and returning from said meetings, provided:

1. That the delegate makes claim for such reimbursement within three months from the end of said meeting of the House of Delegates.

2. That the President approves these expenses as reasonable.

3. That the amount paid to any one delegate shall not exceed one hundred dollars for any meeting, the payment of one hundred dollars being authorized if the delegate's expenses (as above specified) exceed that amount.

4. No expenses of the delegates other than the traveling expenses thus specified shall be paid except by special vote of the Council of The Massachusetts Medical Society.

The motion was favored by Dr. Gay and Dr. F. B. Harrington. Dr. Goss, for the Committee on Membership and Finance, stated that the committee had considered the motion of Dr. Arnold and on its merits recommended its passage, at the same time calling attention to the fact that the expenditures of the Society are fast approaching its income. The Treasurer made a statement of the present condition of the finances of the Society and of the probable expenses of the pending suits for malpractice, now five in number, in charge of the society's attorney.

Dr. Arnold, in explanation of his motion, spoke of the importance of the American Medical Association and its work, and the desirability of each state sending a full delegation of representative men, and explained the custom of other states as regards defraying the expenses of their delegates. The motion was opposed by Dr. Goss on the ground of the expense involved, and on being put to vote it was carried by a voice vote.

Dr. Gay moved: That the Secretary notify one or more of the delegates of The Massachusetts Medical Society to the American Medical Association that a brief report of the transactions of the House of Delegates will be expected at the meeting of this Council following the annual meeting of the said House of Delegates. The motion was carried without discussion.

On motion of Dr. A. T. Cabot it was voted: That a committee of three be appointed by the chair to consider the question: Whether the present rule that assigns Fellows to membership in the District Society where they have their legal residence works satisfactorily to bring out the best efficiency of the society and to meet the convenience of the Fellows.

The President appointed as this committee A. T. Cabot, F. R. Sims and W. L. Burrage.

Adjourned at 1.45 P.M.

WALTER L. BURRAGE, *Secretary.*

## INDUSTRIAL TREATMENT OF THE INSANE AT THE GARDNER STATE COLONY.

THE eighth annual report of the trustees of the Massachusetts State Colony for the Insane at Gardner, Mass., presents some interesting details of the work done at that institution during the past year. Describing the industrial training of inmates of the colony, the trustees say:

"With the completion of the two industrial buildings, we have now excellent facilities for the training of our patients in indoor occupations. Patients are now making and mending all our clothing, mending and making our shoes, and all our men are wearing, during the summer, straw hats made by the patients. Our food supply is, in increasing amount, produced by patients. Apart from a purchase of potatoes, made necessary by a loss through freezing, before our new cellars could be completed, we have raised on our farm all the vegetables that we have used during the past year. In some directions we are now producing more of certain articles than we can use ourselves, and the problem of disposing of them is pressing for solution. For example, patients are making large numbers of old-fashioned mats, braided from rags. These are marketable and can be readily sold. It would seem only just that the proceeds of such sales should be retained by the trustees, to be expended in the purchase of material comforts and little luxuries for the patients engaged in production, which we would hardly be justified in buying from our regular appropriation. We therefore recommend that an act be passed, giving such permission to all institutions for the insane where productive labor is encouraged. The returns from the sales of goods would be ample to pay for the cost of the materials used, and leave a surplus."

The report of the superintendent, Dr. Charles E. Thompson, shows that in 1910 the total number of patients cared for was 685, of whom 460 were men. The daily average was 610, as against 560 in 1908. With regard to the benefits of the industrial method of treatment, Dr. Thompson continues:

"Our aim is to treat our patients by the best systematic treatment — occupation — while assisting and encouraging them to aid in their own support. Two questions suggest themselves: First, how much are these patients benefited by industrial treatment? Second, what has been the return coincident with, but distinctly secondary to, this form of treatment? To the first I would answer that we cannot overstate the benefit derived. Individual cases illustrate this best, but taken all together they are far easier to care for, far less untidy, destructive and troublesome; brighter, more active, contented and cheerful. The requests to leave the colony are few, which alone, to those familiar with our hospitals for the mentally afflicted, tells its own story.

"In our endeavor to check existing dementia we are constantly saying to ourselves that this present dementia, and especially the physical inactivity, should not have been allowed to reach this stage, but the same occupations they are now engaged in should have been open to them directly after their discharge from the acute receiving ward. This leads me to say that industries as an important form of treatment belong more to the acute hospital — to prevent patients becoming pauperized institutionally rather than to stimulate them after they have become so. The second question will answer itself by reference to the tables of farm and industrial products raised."

The work done at the Gardner Colony seems a valuable contribution to the important problem of caring for the insane, and serves to emphasize that, when possible, useful occupation is the best medicine and safeguard for them as for all other human beings.

## CENTENARIANS IN ENGLAND.

A RECENT article in the daily press describes interestingly some alleged English centenarians. A portion of it perhaps deserves quotation.

"Colonel Bower recently died in England. Until a few weeks before his death he rode to hounds and did his duty as a magistrate. Death took him to greater activity in his one hundred and second year. Mr. Henry Tomlinson celebrated about the same time, in Chester, his one hundredth birthday. He shaves himself intrepidly every morning, undergoes the frightful ordeal of a family party and comes out unscathed. An English cricketer for the first time in his life was put in to bowl a match on his one hundredth birthday; he took a wicket. Nor are these isolated instances in England. Mr. Watkins, of Marrow, near Guilford, is one hundred and one; he has labored on the land for seventy years and raised a family on wages that never went beyond 11 shillings a week. There is Mr. Coles, of Croyden, hale and chipper at one hundred and three; he has seen service in the Crimea; he made a melodramatic escape from a burning theater. Above all towers Mr. Mitchell, of Workington, one hundred and five years old. He has a recipe for longevity. He drinks six glasses of beer daily and believes firmly in 'eating as little and drinking as much as possible.'"

That English climate and modes of life should be conducive to longevity is not surprising. Mr. Mitchell's recipe for the attainment of old age, however, is hardly to be recommended.

## TREATMENT OF PHTHISIS BY ANTISEPTIC INHALATION.

IN the issue of the *Lancet* for Jan. 7 is an article by Dr. I. Burney Yeo, of London, on "Pulmonary Tuberculosis Treated by Continuous Antiseptic Inhalation." Dr. Yeo reviews his work on the subject, describes a simple form of inhaler which he has devised and reports the beneficial results of its use in his professional experience. The principal substances which he has used for inhalation are carbolic acid, creosote, spirits of turpentine, eucalyptol, thymol, terebene, oleum pini sylvestris, solution of tar in rectified spirit, tincture of benzoin and tincture of iodine, either singly or in various combinations. This method of treatment for phthisis, which in our own country has been advocated for the past twenty-five years by Dr. Beverley Robinson, of New York City, deserves the attention of the profession.

## Correspondence.

### "A POSSIBLE CURE FOR CANCER." A CORRECTION.

CANCER LABORATORY,
BUFFALO, Feb. 3, 1911.

*Mr. Editor:* My attention has been called to a New York Note in the BOSTON MEDICAL AND SURGICAL JOURNAL of Jan. 26, which states that I have announced that I am prepared to supply a serum which has been shown to be effective in treating cancer. This statement is quite wrong. The despatches, which were taken from an interview regarding the work of the New York State Cancer Laboratory, in which reference was made to certain experiments with vaccine, have been so changed from the original as to entirely misrepresent the facts. We have not announced a cure for cancer, and no reference whatever has been made to a serum. Neither do we believe that vaccination will be beneficial in more than a limited percentage of cases. The results obtained in this laboratory have shown that methods which have given experimental results with animals have some applicability to human cases. There have been very encouraging results in a limited number of cases. The method is not applicable to advanced cases; some cases have done badly under this treatment. The matter is still in an experimental state and it is not possible to place the vaccine in the hands of the profession, nor would it be desirable for cases to come to Buffalo at the present time. The results have been sufficiently encouraging to warrant asking the state to provide a small hospital for the purpose of developing and elaborating this and other methods of treatment.

I would ask you to give publicity to this statement in such way as to nullify, as far as possible, the very serious effects of the report appearing in your journal.

Very truly yours,
HARVEY R. GAYLORD, M.D.,
*Director.*

### RECORD OF MORTALITY

### RESIGNATION.

DR. JAMES MARSH JACKSON has resigned the position of Instructor in Clinical Medicine at the Harvard Medical School.

### SOCIETY NOTICES.

AMERICAN GASTRO-ENTEROLOGICAL ASSOCIATION. — The fourteenth annual meeting of the American Gastro-Enterological Association will be held at Philadelphia, April 19 and 20, 1911.

NEW ENGLAND HOSPITAL MEDICAL SOCIETY. — The New England Hospital Medical Society will hold its monthly meeting in Kensington Building, Boylston Street, Thursday, Feb. 16, at 8 P.M. Section on Surgery. Chairman, Dr. Emma Culbertson. Subject: Report of some interesting cases of the past year at the New England Hospital.

MARGARET L. NOYES, M.D.,
*Secretary.*

BOSTON MEDICAL LIBRARY IN CONJUNCTION WITH THE SUFFOLK DISTRICT MEDICAL SOCIETY. — General meeting. John Ware Hall, Wednesday, Feb. 15, 1911, at 8.15 P.M. "Acute Inflammation of Long Bones: Results in One Hundred Cases from the Pennsylvania Hospital," Dr. Robert G. Le Conte, Philadelphia. Discussion by Drs. E. H. Nichols, James S. Stone, Channing C. Simmons and others. The subject will be illustrated by lantern slides and patients. Light refreshments after the meeting.

DAVID CHEEVER,
HORACE BINNEY,
GEORGE S. C. BADGER,
*Committee on Medical and Social Meetings for the Boston Medical Library.*

THE BOSTON CITY HOSPITAL ALUMNI ASSOCIATION. — The Association will hold its annual meeting on Wednesday, Feb. 15, 1911. Medical and surgical cases will be shown in the amphitheatre of the hospital between 11 and 1 o'clock. The trustees invite the members of the Association to luncheon in the hospital library at 1 o'clock. The annual business meeting will be held at the Hotel Vendome, corner of Commonwealth Avenue and Dartmouth Street, at 6.30 o'clock. Dinner will be served at 7 o'clock. Dr. George T. Tuttle will preside. Tickets, at $2.00 each, may be obtained from the treasurer just before the dinner. The following invited guests have accepted: Dr. Charles W. Eliot, Hon. Herbert Parker, Mr. A. Shuman, Mr. William G. Shillaber and Dr. Francis B. Harrington.

WILLIAM H. ROBEY, JR., M.D.,
202 Commonwealth Avenue, Boston. *Secretary.*

### RECENT DEATHS.

TROW, CORNELIUS GILMAN, M.D., M.M.S.S., died in Sunderland, Mass., Oct. 7, 1910, aged sixty-three years.

FREDERICK COGGESHALL, M.D., M.M.S.S., died in Boston, Feb. 1, at the age of fifty.

DR. BENJAMIN VARNUM HOW, who died last week in Boston, was born at Lowell, Mass. Later he lived in Cambridge, Mass., and in 1876 graduated from the Boston Dental College. Instead of practising dentistry, however, he became an optician. His widow survives him.

DR. DANIEL A. CASELLA, of New York, died on Jan. 30 in the Gouverneur Hospital from the effects of a pistol shot, whether inflicted by himself or another has not yet been determined. In addition to practising medicine Dr. Casella was the manager of several drug stores on the lower East Side, and it was at one of these that the shooting occurred. He was graduated from the medical department of the University of the City of New York in 1890.

DR. CHARLES EDWIN WOOD, of Brooklyn, N. Y., died in the Brooklyn Hospital from cardiac disease on Feb. 1. He was graduated from the medical department of the University of Michigan in 1907 and for a time was in the United States Marine-Hospital Service. This position he resigned a year ago to accept that of physician to the Brooklyn Rapid Transit Employees' Benefit Association.

DR. WALTER H. SNOW, of New Lebanon, Columbia County, N. Y., died from Bright's disease on Jan. 27. He was born at Athol, Mass., on Dec. 27, 1859, and was graduated from the medical department of the University of the City of New York in 1881.

DR. HUGH CAMPBELL HENDRY, of Newark, N. J., died on Jan. 28, from cardiac disease. He was born in Glasgow, Scotland, in 1849, and was graduated from Bellevue Hospital Medical College, New York, in 1872. For a time he was surgeon to the Newark police department.

DR. STANLEY DOUGLAS CURRAN, of New York, who had been in ill health for some time, committed suicide by shooting on Feb. 4, while in a fit of despondency. He was forty years of age, and was graduated from Bellevue Hospital Medical College in 1896. At the time of his death he was physician to the University and Bellevue Clinic and to the Harlem Dispensary.

# THE AIMS AND POSSIBILITIES OF NEUROLOGICAL HOSPITALS.*

BY PEARCE BAILEY, M.D.,

*Physician to the Neurological Institute of New York.*

A DISTINCT change has come over the study of neurology. Fifteen or twenty years ago, the neurologist was occupied chiefly with anatomical studies and their clinical expressions. Aided by the pathological anatomist, he confirmed the localization of lesions, determined tracts and was concerned largely with the organic nervous diseases. Now there is an anatomic branch of neurology, as much as there ever was; we still have to localize tumors and recognize anatomical lesions, but the scope of this so-called specialty has spread far beyond these narrow boundaries. To-day the sphere of the neurologist who fulfills his obligations is that of the counselor in the widest sense. He must first of all be a physician. After that, he must know enough of psychological technic to apply it and deduce results; he must be chemist enough to understand when chemical reports are indicated, and be able to interpret their meaning; he must be sufficiently conversant with the detailed application of physical remedies — exercise, baths, electricity, occupations, climate etc. — to prescribe them when necessary; he must also be a teacher in spite of the fact that the facilities for bedside teaching in neurology in this country are most inadequate; and, in addition to all this, he must be man of the world enough to recognize and appreciate the temptations, the trials, the frailties and the possibilities of the unstable class of patients who consult him.

The position of philosopher and friend has been more or less forced upon him by the dying interest in religion and by the example of physicians in other lines, who have been too much occupied with contending with physical diseases to pay much attention to the possibility or extent to which the results of psychic and physical therapeutics might be enhanced if more attention were paid to them.

Everywhere in medicine and surgery may be seen a lack of effort to repress the unnecessary material idea. A telling example of this may be found in the sanatoria for tuberculosis. Here the introduction of proper physical exercises, rest, fresh air, etc., has worked miracles; but their value would be still greater if more attention were given to some simple rules in psychology. In many of these sanatoria, little effort, apparently, is made so suppress the painful paraphernalia surrounding the great white plague. The patients sit on the porches, take their own temperatures, and discuss their symptoms; their concentration on disease and lack of systematic occupation militates against the success of any method of treatment. I recall one woman with tuberculosis who was an excellent illustration of this fact; both of her lungs were affected and she went to a sanatorium, where she kept track of her own temperature and discussed her symptoms to such an extent that she finally became a hypochondriac on tuberculosis and was sent to New York for treatment. Here her thermometer was thrown away, no further examinations of the lungs or sputum were made, and under a purely neurological régime she gained in weight and appetite, the fever left her, and she has now (three years after) apparently entirely recovered. Her lungs have not been examined, but why should they be?

To meet the task set before him, the neurologist must have for the field of his activities some central workshop where he can study his patients, communicate freely with those who work with him, carry out his experiments and impart to others his methods of work and the results of his experience.

It was with these ideas in view that a year ago we followed the lines of all modern concentration of effort and endeavored to establish a center of neurological activity. It seemed only fitting that we should have in New York an institution of this kind; there are many varieties of laboratories of research; there are hospitals given up to surgery, and there are other hospitals, well-equipped, devoted to almost every branch of medicine, but there has not been and there is not yet a neurological center with the equipment and of the importance that the subject merits. Perhaps the National Hospital in London comes closest to this idea, and the work it has done can be found in the biographies of the great men who have been connected with it, and in the history of modern neurology, but even there are not realized the full possibilities of a neurological establishment. I will, therefore, attempt to outline what our views are as to what such an institution should be.

In the first place, let us consider the financial aspect. The word "hospital" is derived from the Latin *hospes*, a guest, and the general idea at first was that hospital patients should be treated free. But with the distribution of wealth and possibilities, this idea has become archaic, so that now free treatment should be avoided whenever possible. This is especially true with nervous patients, upon whom the effect of *quid pro quo* stimulates self-reliance and hastens convalescence. It has been the rule with us that ward patients should pay when they can; they may not be able to pay the full rates, in which case they can be graded down, and only about one third or one fourth of our ward patients have been treated free. Under this plan, they make fewer complaints and are better satisfied, thinking that they are receiving their money's worth more than they would as free patients.

I think every hospital of this kind should have private rooms for patients who can pay as much or more than they would be charged in hotels. These patients, besides materially aiding in maintenance, are usually possessed of more than ordinary intelligence, and are likely to become interested in the work of the institution and to disseminate a knowledge of what is being done

* Read before the "Doctors' Club," Jan. 17, 1911.

there, and they may, eventually, on account of the latter, make a substantial gift to the hospital. The exact character of such an organization will depend largely upon the size of the community in which it is. The most desirable is an individual plant with an equipment all of its own, which may or may not be part of a general hospital, where laboratories, wards, private rooms and dispensary, can all be gathered together and all controlled under a single staff and management. This is only possible in large cities, but if well-planned and economically administered, such an institution in a large city may be run without a too great disparity between its budget and its income. The most certain income will be found to accrue from the private rooms of moderate price ($25 to $30 a week) in which persons with incurable disease can be made comfortable for any definite period of time. In rooms of this character, no physician's fees should be charged. In smaller communities, it may be found impracticable to run a separate institution. Under these circumstances, a neurological ward may be equipped in connection with some general hospital. There may be some struggle at first to secure the co-operation of the existing medical board of the hospital in agreeing that all neurological cases, medical and surgical, shall be sent to the neurological ward.

Such an agreement, however, should be reached before the plan is put into operation, and the equipment of the ward in the way of apparatus, house staff and a head nurse or a superintendent of nurses must be individual. The individual personnel seems imperative. The house officer should not be connected with the general service of the hospital. To do his work properly, one man cannot care for over ten or fifteen patients in an acute service, and although it may not be necessary for his term of service to be over a year, while he is on neurological duty he should have no other. There should also be a competent and well-trained woman on a good salary in charge of the nursing of this ward. The nurses under her may serve for periods of from three to six months, but while serving in the neurological ward they also should not have duties elsewhere. It is only by this constant application and association that they may learn the point of view and the routine essential in the treatment of nervous diseases.

An institution of this kind should be divided into a city plant and a country plant. The former should be in the nature of a reception hospital for the purposes of diagnosis, surgical treatment, for the treatment of cases that are likely to be of short duration and for the care of patients with wrong ideas about their health, who should be kept long enough to counteract improper psychical influences and erroneous theories on physiology.

The country plant or sanatorium should be fitted up for the care of chronic and charity cases and those not suitable for the city plant. This includes those who are crippled and those for whom outdoor life and occupations are indicated. The mental cases must be provided for chiefly in the country, partly for economy and also because the Lunacy Commission refuses to license an institution for the care of these patients in the city unless it has sufficient grounds surrounding it. The country institution for the insane may be made a substantial source of income.

The city branch, as an ideal institution, should also have some provision by which, perhaps with the co-operation of the state, the class of children who ultimately develop criminal tendencies could be taught how to live in the open and how to occupy themselves outdoors.

When the Neurological Institute was opened, I thought the necessary surgical work could be done at some of the other hospitals, but during the past year we have had occasion to do nine primary craniectomies and thirteen primary laminectomies, besides numerous other operations, and I am now convinced that our surgical department is one of the most important of the city plant.

The equipment of the hospital, particularly that of the city plant, should include all the necessary physical appliances for exercising, the Fraenkel movements, electricity, hydrotherapy, hot-air, occupation, etc., and these should be very complete.

For the purpose of concentration of work, these adjuncts must be directly connected with the hospital, and by this means, also, physicians gain an intimate knowledge of therapeutic procedures, regularity of treatment is enforced, and the means for the collection of valuable data is afforded. Thus, we may eventually be able to determine whether the benefits apparent from such therapeutic measures are simply those of suggestion or have a distinct physiological basis. These various appliances, as well as a careful record of the pulse blood-pressure reactions before and after them, even if they do no direct good, give the nervous patient something to think about, to put his teeth into and occupy his mind. It convinces him that he is there for some purpose. He has less time to think about his own troubles, is kept busy, and even if they serve no other purpose, these various mechanical contrivances are of service in that respect.

Broadly speaking, the most important purpose of the city plant of a neurological hospital is that of diagnosis. In such an institution, one is no longer forced to venture an immediate diagnosis. The more one sees of neurological cases, the more one sees how impossible it is to make a satisfactory diagnosis and arrive at a rational plan of treatment without prolonged observation, and we now seldom endeavor to make a diagnosis in less than three days, or even a week, or longer.

The laboratory connected with an institution of this kind should be a clinical laboratory, of course, and it is apt to be a very busy place, as constant demands are made upon it for the examination of urine, blood, feces, serum, etc., in relation to conditions of disturbed metabolism. In addition to this, there should be an experimental laboratory. So far as I know, there is no place in New York where neurologists can make

satisfactory experiments in their particular lines of work, and this country generally is deficient in that regard. As an illustration of the value of experimental work in neurology, I might cite the case of Dr. Harvey Cushing, of Baltimore, who is himself a surgeon, but who has made more impress in this country upon the surgical treatment of diseases of the brain than any man of our time. He has succeeded in doing this because he has been able to secure for his own use a surgical service connected with an experimental laboratory.

The educational advantages of a neurological institute should be very great. The atmosphere surrounding such a neurological center, and the opportunity for discussion, stimulates to new effort, and makes for a spirit of exactitude, and does away with the slipshod methods that are apt to creep into our work. It affords very favorable opportunities for clinical meetings, during which patients in the hospitals, with their complete histories, can be presented and discussed.

At one of the recent weekly conferences at the New York Neurological Institute, there were presented four cases which had been operated upon for spastic conditions in the new operation of section of the posterior spinal nerve roots. It would have been impossible to have collected so many instances of the advantages and disadvantages of this operation except in connection with a neurological hospital, and the lessons we learned from this exhibit should prove extremely useful to all of us and to our patients.

Also, in a central plant of this kind, one is able to obtain skilled help in difficult cases, and in no instance is an operation recommended until every phase of the case has been carefully considered by several competent men.

The education of assistants proceeds rapidly and thoroughly in an institution such as I describe. They see the patients, not only in the outdoor department, but in the wards of the hospital; they get the results of the laboratory findings; they see the patients operated on; they have an opportunity to follow their subsequent career. The assistant, in other words, gets the same training that the house physician of a general hospital gets during his term of service, together with the constant association with older men.

Throughout the country, one hears complaints of the lack of well-trained recruits coming to fill the neurological ranks, and we feel that it is necessary for a very radical change to come over the facilities offered students for studying nervous diseases if American neurology is to maintain the standard it now has.

An institution of this kind should attract medical students, especially post-graduates, from different parts of the country, and if it is properly equipped and conducted it will no longer be necessary for American students to go to Europe for special training in neurology. It also provides a valuable training school for nurses in this branch of medicine. A good nurse in neurology is just as important as a good nurse in surgery. She must learn not only to absolutely abandon all bedside gossip, to avoid mention of anything which may frighten or disconcert her patients, to be cheerful, optimistic and resourceful, to be observant of special symptoms which often enough a physician can never observe himself, e. g., Jacksonian epilepsy, and, furthermore, to carry out orders with the military precision which is at the basis of all neurological therapeutics. As it is, we have no specially trained nurses in this branch outside of those in the state hospitals. Possibly these nurses would not need as complete a technical equipment as those who are intended for general work, but they should receive some special education in nervous diseases, partly for what they are to do, but especially for what they are *not* to do, for the blundering of tactless nurses is not the least of the neurologist's troubles.

The last point I wish to mention in connection with this subject is the one that has puzzled me the most, and it is this, — that neurologists should concentrate their efforts to take a more active part in the civic life of the community, which they can only do through perfected organization. Largely through the efforts of Dr. Richard Cabot, the necessity of a social service department in every medical clinic has passed the stage of argument, is accepted as the most effective form of modern medical treatment, and, it is needless to say, no neurological institute is fully equipped without such an accessory. But in addition to what such an institute may do for individuals, by means of social service work, it had a wide future in fostering preventive measures. The health officials send their nurses through the tenements to ferret out cases of tuberculosis and instruct the people how to prevent it; the ophthalmologists have succeeded in securing legislation to prevent the occurrence of ophthalmia neonatorum and check the spread of trachoma; but thus far, the neurologist has been strangely silent in suggestions as to how to cope with the unstable character in childhood, and in co-operating with others in the prevention of crime and alcoholism. Among the inmates of the Elmira Reformatory it has been found that nearly 85% are so feebleminded that they are incapable of learning a trade. Such cases should pass through a neurological institute. Let these children be recognized and provided for before they reach the criminal age; let us find some means of sending them to the country early, where they could be taught to lead useful lives, instead of filling up our prisons and reformatories. This question of social service should receive more serious attention from a neurological point of view than has hitherto been accorded to it.

In concluding, I refer briefly to the work of the Neurological Institute during the past year. From Dec. 1, 1909, to Dec. 1, 1910, the number of patients treated in the hospital was 839. In the dispensary we have treated 3,136 new patients, and the visits of these patients numbered 13,198. Of those who received special treatment, hydrotherapy, mechanical treatment, etc., the highest number in one month was 1,200.

# THE NEW NEUROLOGICAL SERVICE AT THE BOSTON CITY HOSPITAL: ITS FIRST YEAR'S WORK.

BY PHILIP COOMBS KNAPP, A.M., M.D.,

*Clinical Instructor in Diseases of the Nervous System, Harvard Medical School; Physician for Diseases of the Nervous System, Boston City Hospital.*

IN May, 1909, the trustees of the Boston City Hospital voted to establish special services in the wards of the hospital for diseases of the nervous system and diseases of the skin. Twenty beds were assigned to the neurological service and six to the dermatological. The two services have house officers in common, who serve four months in the out-patient department and eight months in the wards, the junior house physician taking charge of the dermatological cases. On the 15th of July, 1909, the first patient was admitted to the neurological service. A brief consideration of the work of that service during its first year may be of some interest and may also give some facts bearing upon certain questions now under discussion.

Three hundred and eighty-three patients were admitted to the service during the year. Of these, 158 were suffering from some form of disease of the brain, — 110 of them from some vascular lesion, hemorrhage, thrombosis, embolism or arteriosclerosis, 11 from meningitis, 10 from edema of the brain, 9 from syphilis and 7 from tumor; 40 had some disease of the spinal cord, — 14 tabes, 7 poliomyelitis, 4 myelitis and 4 tumor; 24 had disease of the peripheral nerves, — 19 of them being cases of neuritis; 53 had some neurosis, — 20 hysteria, 12 epilepsy, 10 chorea, 3 neurasthenia and 1 psychasthenia; 39 were alcoholic cases; 21 were cases of mental disease, — 7 senile dementia, 5 dementia precox, 4 general paralysis and 4 maniacal excitement; 48 cases were of various non-nervous affections.

The mortality was heavy, owing to the large number of cases of apoplexy, brought in often in a moribund condition. There were 110 deaths. Fifty-eight died of some vascular lesion of the brain, 8 from meningitis, 10 from edema of the brain and 2 each from syphilis and tumor, — a total of 80 deaths from cerebral disease. Of the other deaths, 6 were from some form of spinal cord disease, 2 from neuritis, 2 from chorea, 1 each from epilepsy and exophthalmic goitre, 3 from alcoholism and 1 each from dementia precox, general paralysis and maniacal excitement. Thirteen cases died of some non-nervous disorder. Thirty-seven autopsies were obtained, 19 of which were medico-legal.

In a recent article pleading for the establishment of neurological hospitals and neurological wards in general hospitals, Collins and Bailey [1] say that "in all America there is scarcely a general hospital with neurologic (*sic*) wards worthy of the name." With their plea for a better recognition of neurology and with their condemnation of the internist for his wilful neglect of the subject, I would absolutely agree, but there has been at the City Hospital in Boston for over a year this service for diseases of the nervous system which, combined as it is with the out-patient department, which treats seven or eight hundred cases annually, affords at last in Boston a proper opportunity for neurological work and for the training of students interested in neurology. The old service for nervous diseases at the hospital, which existed from 1877 to 1886, did much for neurology in this country in the early days, and its abolition, for which no defense can be made, was a serious blow to scientific progress in medicine. The restoration of that service, combined as it is with a large out-patient clinic, promises much for the future. The patient suffering from nervous disease who enters the hospital to-day can now receive the special care and treatment of which he has been so long deprived, but to which, in a city institution, he is as much entitled as the patient with uterine or ocular disease. The student wishing to make special study of neurology now has an opportunity for hospital work in that special branch of medicine; and the neurologists on the staff of the hospital at last have the opportunity for proper study of neurological cases, of which they have so long been unjustly deprived.

The actual work of the service during this first year has brought out some rather interesting facts. The first item of interest is the remarkably small proportion of cases suffering from the various neuroses, — less than one seventh of the total number admitted. A number of these, many of the epileptic and hysterical cases, came in rather as emergency cases. Only three cases of neurasthenia and one of psychasthenia are recorded. In the out-patient department, however, the neuroses make a very large proportion of the total number treated, — usually over one third. These facts are of some significance in view of the recent plea that the state should establish a hospital for cases of "nervous breakdown." The vast majority of such cases as have presented themselves at the hospital during this year have been able to receive treatment as out-patients and have not seemed to require treatment in the wards of the hospital. I must confess that it has been a surprise to me, during my own service, to find how few neurasthenic patients were admitted to the service, for I had expected that they would form as large a proportion of the cases in the wards as they did in the out-patient department. It is, of course, somewhat premature to draw conclusions from the statistics of a single year, but very many cases of neurasthenia and psychasthenia do better if they can be in the world and can do certain work therein under wise counsel than they would do within the walls and under the deadening routine of an institution.

The second interesting feature of the new service is its relation to the psychopathic cases and the psychopathic hospitals. The statistics given above do not show this adequately. There were 31 cases diagnosticated as "alcoholism," which were cases of delirium tremens, alcoholic hallucinosis or alcoholic confusion, and 21 cases of the different forms of actual mental disease,

[1] Jour. Am. Med. Asso., vol. lv, 393, July 30, 1910.

paresis, dementia precox, etc. Many of the 19 cases of neuritis had Korsakow's psychosis; the 10 cases of "edema of the brain" (usually a post-mortem diagnosis) were for the most part alcoholic cases with "wet brains," presenting various mental disturbances. Some of the hysterical and epileptic cases, also, had marked mental disturbances, and various other cases were more or less delirious. On the whole it is a safe statement to say that over 100 patients presented, during at least a part of their stay in the hospital, some form of mental disturbance. This disturbance was often transitory, and comparatively few of them were finally committed to a hospital for the insane, but the hospital has cared for a very considerable number of patients in this service for whom a "psychopathic hospital" is urged, and, with a further development of the service, it can care for still more, and must necessarily care for many cases, even after the "psychopathic hospital" is opened.

That the new service has many problems to meet in the future, in the way of administrative detail, and that it needs further development along certain lines, is obvious; it is my object at present merely to indicate what has been done in this first year and to show what opportunities the Boston City Hospital now affords for neurological study and teaching.

## THE YOUTHFUL PSYCHOPATH.*

BY J. W. COURTNEY, M.D., BOSTON.

THE purpose of this very brief communication is to stimulate interest in a subject which I believe to be quite as important to the pediatrist as it is to the neurologist. Theoretical considerations I shall endeavor to avoid, for I know you will heartily agree with the statement that we are already surfeited with theories which mark the record for altitude in flights of psychologic fancy.

In textbooks and other writings on the subject of certain psychoses — notably paranoia and dementia precox — and certain psychoneuroses, clinically designated as hysteria and psychasthenia, the statement is frequently made that these disorders are due to factors which become active between the ages of puberty and maturity, and that their outbreak generally takes place between these two periods.

In my opinion this statement is both erroneous and misleading. It is true, to be sure, that the disorders mentioned frequently do not reach their maximum intensity until some time between the ages of sixteen and thirty. But to you who are constantly observing the ailments of infants and young children, it must be a matter of observed fact that unmistakable evidence of the existence of these disorders is very often present at a tender age.

As to causation, I believe you will agree that in practically all cases presenting this early evidence the hereditary origin of the trouble may be readily established. Indeed, actual statistics show that at least 75% of the cases representing these adynamic types of nervous and mental disturbance come from families in which mental alienation in some form or other has appeared in more than one generation. It is also an established fact that ancestral alcoholism, tuberculosis and syphilis must be given a prominent place in pathogenesis. Furthermore, it is often found that the father or the mother of the psychasthenic or the hysteric is afflicted with the same trouble and that the patient is apt to bear a strong physical resemblance to the afflicted parent. Finally, it may be stated that even in cases where the immediate forbears have no actual nervous disorder, they nevertheless often present such stigmata of mental and physical insufficiency as timidity, lack of balance and sound judgment, indecision and morbid emotionalism.

From my own personal experience and observation I am convinced that psychasthenia, hysteria, paranoia and dementia precox are identical in pathology and that in the overwhelming majority of cases they are hereditary in origin and slow in evolution. I am furthermore convinced that unequivocal clinical signs of their presence are always observable as early as the fifth year of life — in certain cases even earlier; and it is to the victims of these manifestations that I have applied the not altogether satisfactory term — "youthful psychopath."

Assuming that my convictions are well-founded, of what importance are they to the pediatrist? They are of paramount importance, because he is far more apt than either the neurologist or the alienist to come in contact with the afflicted child when the disorder is in its inception or but slightly advanced.

Those of you who are skeptical with regard to the value of neurological therapeutics may ask yourselves what practical results the writer of this paper expects to follow an early recognition of the disorder.

To such my answer is that early recognition offers opportunities for achievement along the lines of prophylaxis and treatment quite as signal and brilliant as any obtained in the combat with tuberculosis.

I venture this assertion because pathology fails to reveal to us that the condition underlying the disorders in question is other than an adynamic one, and with such a condition, even though it be of hereditary origin, we have every reason to hope for a successful struggle.

Before we can put into action our prophylactic and therapeutic forces, however, we must be sure that we thoroughly understand the youthful psychopath mentally, morally, emotionally and physically.

There is nothing absolutely distinctive about the bodily habit of such a child, although it is very apt to have a slender musculature, a narrow chest, scaphoid scapulæ, drooping shoulders and a vascular hypotonicity, with the vasomotor ataxia which so commonly accompanies this last-mentioned condition.

In a certain percentage of cases there is a differ-

* Read at the twelfth meeting of the New England Pediatric Society, held in Sprague Hall, Boston Medical Library, Nov. 26, 1910.

ence in the size of the pupils, most noticeable when the eyes are turned away from the light. The pupils are, nevertheless, always regular in outline, the response to tests of light and distance is prompt and alike in both eyes, and concentric limitation of the field of vision is invariably absent. The remaining sensorial, as well as the sensory, stigmata are also lacking.

Owing to the vasomotor irritability the susceptibility to atmospheric conditions is very marked. If the child happens to be outdoors when the weather is at all cold, its extremities quickly become mottled and painfully cold and numb. If it chances to go indoors while in this condition, the heat of the house very soon causes a change from vasoconstriction to vasodilatation, with the result that the ears, cheeks, hands and feet tingle and grow uncomfortably hot and red.

In many cases the enthusiasm for childish games of the outdoor sort is not in the least abated. On the contrary, they are entered into with intensity and vehemence, but the emotional reaction is so marked that appetite is abolished and sleep is disturbed by vivid dreams. So slight, in fact, is such a child's power of inhibition that after a hard day's play it will toss and tumble about the bed all through the night, grind its teeth, cry out aloud or from time to time mumble disjointed phrases.

In other cases a distinctly anti-social tendency is early exhibited. Where this exists, the child has no desire for outdoor play with other children, but prefers to remain at home with a parent or nurse. Both these types exhibit marked propensities to sleep-walking and similar automatic acts, and also to night-terror and bed-wetting. Furthermore, in both types, again, the eruption a tooth or the onset of even a mild attack of one of the exanthemata is very apt to be ushered in by convulsions.

Intellectually the psychopathic child is, as a rule, precocious to a marked degree, but unfortunately its intellectual nature is so completely overwhelmed by its emotions that, both in school and company, really dull children of its own age appear actually brilliant by comparison.

I should like to make manifest to you the full extent to which the morbid emotionalism of this child overshadows its intellectuality, shapes its character and compels its thoughts and actions, but I confess that my powers of expression are entirely inadequate to perform such a task satisfactorily. However, the facts, although stated in a clumsy and roundabout fashion, are about as follows: One of the most powerful of the elemental human emotions is fear. In proof of this one has merely to observe the expression of this emotion in the newborn infant. No experience hypothesis in explanation of this phenomenon is tenable. Clearly, the fear-emotion is a heritage transmitted by countless generations, and a child comes into the world with it as firmly embedded in the meshes of his brain cells as the deciduous teeth are in the gums. This is true of even the most normal child, but is infinitely truer of the adynamic. Weakness and fear go hand in hand, and in the youthful psychopath fear is the emotion that dominates all cerebral activity.

If we bear this fact in mind, many of the phenomena exhibited by it become readily intelligible. Fear, like the other emotions, has a very definite form of physical expression, such as pallor, cries, palpitation of the heart, muscular trembling and relaxation of the sphincters. With these are often associated some voluntary or semi-voluntary movements of a muscle or group of muscles which evidence an attempt on the part of the affrighted individual to escape from a terrifying object or situation. In the youthful psychopath certain of these semi-voluntary defense movements are habitual and constitute the *tics* with which your clinical experience has familiarized you. The other phenomena are not habitual, but are frequently occasioned, to some degree at least, by various agents which tend to bring the fear-emotion to a crisis. These agents are many in number, but the most common are such natural phenomena as thunder and lightning, the noise of fire-arms, high places, crowded or solitary localities and so forth.

The effect of fear upon the child's habit of thought is very striking. The necessary brevity of this paper renders a detailed description of this peculiarity impossible. Suffice it to say that every occurrence that comes to the child's attention and every chance remark that is made within its hearing is seized upon and invested with a personal significance that is always sinister. A single example will illustrate this point. A psychopathic child of six years now under my observation recently heard her father say that in his belief a war between this country and Japan was bound to come. At the time there was no reason to suppose that she had paid any particular attention to what was said, but a few days later, while she was in a down-town store with her mother, she saw two Japanese, and immediately seized her mother's skirts with every evidence of terror. In surprise the mother questioned her closely as to the cause of her fear, and the interrogation finally brought out the fact that the child was convinced that war with Japan had begun and that her life was imperilled by the presence of the Japanese in the store.

The effect of fear upon character formation is equally striking and interesting. In the company of normal children or of adults not of its family, the youthful psychopath is shy and diffident to a marked degree. If its over-exalted sensibilities chance to be wounded by a child of its own age, it invariably has recourse to tears rather than to retaliation. When it is spoken to by grown-ups who are strangers to it, it changes color and stammers out a reply. And when, under observation of which it is conscious, it attempts some performance that calls for nice muscular adjustment, its power of co-ordination is so crippled that the result is a dismal failure.

In the home, on the other hand, this same child is self-willed and domineering. It brooks neither reprimand nor repression, and the slightest contrariety, from no matter what source, calls

forth an emotional outburst which, in all essential details, corresponds to an hysterical convulsion.

Other striking peculiarities of character are also frequently exhibited. There is no gainsaying the fact that even the most normal child is possessed of a transitory criminality. We are all aware that such a child will lie and steal; that he may be unmoral and without affection; and that he may be cruel to the feeble and to animals. But in the youthful psychopath, owing to its very limited powers of inhibition, these traits are vastly more accentuated, and tend to permanency. In this same child you have the habitual nail-biter and the precocious masturbator, for which peculiarities I have at this time no special explanation to offer.

Permit me to lay emphasis on the fact that all these abnormal characteristics — mental, moral and physical — which mark what I have somewhat inaptly termed the "youthful psychopath," may be brought to light by careful observation and persistent investigation, in subjects between the ages of five and ten years.

Once they are brought to light we may determine by their grouping in a given case whether we are dealing with hysteria or psychasthenia, paranoia or dementia precox; and by their intensity and fixity whether the disorder is merely nascent or in full process of evolution.

All four of these clinical forms present certain features in common, but each is marked by peculiarities that are sufficiently distinctive. In psychasthenia the fear-emotion colors all the mental operations to a certain degree, but the counterbalance of judgment is never lost, so that obsessive ideas are not transformed into delusions; and morbid impulses seldom become overmastering. In paranoia the obsessing ideas tend early to become systematized and to focus upon the subject of the sufferer's personal safety and liberty. Fears which the psychasthenic experiences only in certain places and at certain times, and which lead merely to obsessive ideation, are experienced by the paranoiac at all times and in all places. And instead of obsessions, actual delusions of being followed and persecuted, after a time, completely govern the victim's reaction to his environment.

Dementia precox is to be feared where the powers of inhibition remain markedly weak and the growth of the moral sense does not keep pace with growth in other directions. Here the predatory and animal instincts of the child occupy the foreground of the clinical picture, and we find it to be a shameless liar, a confirmed thief, a natural vagabond, a masturbator and the personification of cruelty.

In the youthful hysteric the obsessive and impulsive tendencies are by no means so marked and obvious as they are in the psychasthenic, the paranoiac and the precocious dement types. The morbid phenomena exhibited by this child are not constant but periodic, and are usually confined to somnambulism and other automatic acts, and to violent emotional outbursts accompanied by convulsive movements, which may be followed by temporary palsy and contracture of limbs or segments of limbs.

After we have determined that we are dealing with a potential or actual victim of some one of the four forms of disorder under consideration, what may we hope to accomplish by treatment? I have already expressed the belief that the underlying morbid condition is a simple adynamic one, but even in a simple adynamic condition of the nervous system we are confronted with a metabolic problem that is by no means easy of solution.

Nervous energy, like electricity, is practically unknowable in essence, and yet we are aware that it is, in part at least, a form of motion liberated from substances with which the body is sustained.

This fact turns our attention at once to the physical needs of the afflicted child. To you who have made such advances in the chemistry of juvenile dietetics, I shall not venture to particularize with regard to food selection. The practical demand is for a diet that offers the highest possible percentage of energy production and is at the same time small in bulk, easy of digestion and assimilation, and inconsiderable in waste.

With the diet problem settled, attention should be turned to faulty postural habits. These defects are best eradicated by participation, enforced if necessary, in outdoor games, which are supervised by a tactful nurse or parent. Regular gymnastic systems are entirely inadvisable because the monotonous repetition of any movement quickly wearies the child both mentally and physically.

When the physical system begins to show signs of increasing vigor, we may safely attempt to divert the child's mental activities into normal channels. This, for several reasons, is the most difficult part of the task. First, because it is oftentimes well-nigh impossible to gain the child's confidence sufficiently to enable one to bring its obsessive ideas to light; second, because the parents themselves are of flabby personality and cannot be made to understand the full significance of the child's condition; and lastly, because environing conditions in general are unfavorable. However, with tact and patience much may be accomplished.

No definite rules can be set down for this portion of the treatment, but the guiding principle should always be disciplinarian in character. The child should never be made to feel that it is any way abnormal and should never be segregated. On the contrary, the social instinct should be fostered and strengthened in every possible way, care being taken that the associations formed are with healthy children. The nipping in the bud of anti-social tendencies is of vital importance, for their persistence in fully developed psychasthenia is a source of the most poignant suffering, and in paranoia a menace to public safety.

The panphobic tendencies of the youthful psychopath must also be eradicated. In this task the personality of the individual in charge of the child counts for everything. Such a person must be fearless, self-repressed, sympathetic yet firm.

By such qualities the child's confidence is easily won, and it becomes communicative with regard to its fears. When these are known, it should be the aim of the person in charge to rid the child of them by persuasion and by personal example. Ideas of courage in every form should be implanted in the childish imagination and their growth fostered in all possible ways. Depressing tales of a supernatural and terrifying character should be sedulously kept from the child's ears. The threatened invocation of the police or of bogeys for the purpose of checking rebellious tendencies is to be characterized as little short of criminal.

The religious training is also a matter of prime importance and care should be taken to inculcate the notion that the Deity is not revengeful and constantly on the alert for the opportunity to consign His erring children to a material hell.

The importance of both these suggestions becomes manifest when we consider that some of the most distressing fears of the full-fledged psychasthenic center about hobgoblins, supernatural phenomena, the guardians of the law and the wrath of the Creator.

For the tics and for actual convulsive phenomena, the judicious use of sedatives is strongly to be recommended. But for many of the other phenomena exhibited — like stubbornness and temper — I recommend, in spite of the implied heresy, a good, sound spanking.

I am fully aware that I have not covered all the points that a subject such as I have chosen naturally raises. I trust, however, that whatever I have omitted will be fully taken care of in discussion.

In conclusion, permit me to state again my sincere belief that the morbid conditions under consideration are, to the observant, fully obvious at an early period of life and that, by proper treatment, their course may, in many cases, be arrested and many a mental wreck thereby averted.

## SOME CLINICO-PATHOLOGICAL DATA ON BLADDER TUMORS.*

BY LINCOLN DAVIS, M.D., BOSTON.

ABOUT four years ago I made a study of 41 cases of tumors of the bladder collected from the records of the Massachusetts General Hospital.[1] I should like to recapitulate now some of the points made in that analysis, and bring the figures up to date.

In only 28 of these 41 cases were microscopical examinations of the specimens recorded. Twenty-five belonged to the epithelial group, 2 were sarcomata, 1 was a myoma, showing a great preponderance of epithelial tumors. Seventeen of the specimens of epithelial tumors which had been preserved were personally studied; 6 of these showed satisfactory evidence of epithelial infiltration of the bladder wall and were classed as carcinomata; 11, or nearly two thirds, were regarded as papillomata.

A total of 37 cases were operated upon, 9 resulting fatally within a month or while still in the hospital, giving an operative mortality of nearly 25%.

In none of the malignant cases was a radical operation, as it is now understood, attempted, but merely such palliative measures as curettage, cauterization and partial removal resorted to, with the result that death from the disease occurred in every case within six months.

Of the 28 patients who survived the operation, 26 were traced. Fourteen, or just 50%, died of the disease, 1 of these surviving for five years in spite of repeated recurrences before finally succumbing. Twelve patients, including those who died of other diseases, had no recurrence so far as could be learned. Nine are known to have survived the operation one year. Seven survived the operation two years. Five survived the operation eight years. Three of the latter died of other diseases, leaving 2 patients living and well at the time of the report, respectively eight and ten years after operation. Of the 5 patients who survived for eight years, in only 3 were there pathological reports on the specimens removed; 1 was a myoma, 2 were papillomata.

Of the 8 cases of papillomata in which the specimens were personally studied, 1 died as the direct result of the operation, 1 died of intercurrent disease eighteen months later without evidence of recurrence, 1 died two months after secondary operation for recurrence, 1 five years later of recurrence. One case reported perfect health one year after operation, not heard from since. One case cannot be traced; one case is well eight years after operation. One case operated on by Dr. A. T. Cabot in 1892 and again in 1897 for recurrence has remained well up to the present time, thirteen years since the second operation.

These figures indicate a considerable period of immunity, if not an ultimate cure, in a respectable proportion of cases of papillomata of the bladder after simple excision of the growth through a suprapubic cystotomy wound.

At the time of writing my former paper on this subject I had a personal operative experience of a single case; since then I have operated on 15 cases of bladder tumors.

Of these more recent cases, 9 were papillomata which showed no evidence of infiltration of the bladder wall as far as microscopical examination of the specimens permitted of determining this point. The tumors varied in size from a large pea to an orange, and in number from a solitary growth to a dozen or more. No recurrences have been reported as yet. Two patients are reported well respectively four and two and one-half years after operation. Four reported themselves as well one year after operation. One case operated on a year ago has not been traced; 2 cases are very recent.

In one case in which there was one large papilloma and five smaller ones, Dr. Whitney's report stated that there was a solid mass of epithelial cells apparently in the lymph spaces

* Read before the New England Branch of the American Urological Association, Nov. 29, 1910.

[1] Ann. Surg., April, 1906.

of the pedicle of the larger growth. The smaller ones appeared quite benign. This patient is now under treatment in the Out-Patient Department for mild cystitis; he has been cystoscoped several times and there is no recurrence. It is one year and six months since his operation.

Three cases were frankly cancer of the nodular, infiltrating kind; all recurred within a year. In only one was a radical transperitoneal operation performed with excision of the growth, and entire thickness of the underlying bladder wall. In the 2 other cases curettage and cauterization through a suprapubic incision was all that was attempted. Two cases were of quite unusual interest; one[2] which has been previously reported was of a pedunculated growth springing from the prostatic urethra and was found on section to be a papillary cystadenoma. The prostate was removed in this case and showed a similar condition. The growth, therefore, is not properly to be classed as a primary tumor of the bladder, as it was of undoubted prostatic origin. The other case, a recent one, was of a peculiar cystic growth, the size of an egg, which was attached close to the internal urethral orifice, though it did not seem to be a part of the prostate. Dr. Whitney has recently pronounced it to be a cystic growth of undoubted prostatic origin.

There was no operative mortality in these 15 cases. Transperitoneal cystotomy was done in 5 cases, and simple suprapubic cystotomy in 10.

My own experience and that of others with which I am familiar forces me to take a gloomy view of infiltrating cancer of the bladder, yet I believe that here as elsewhere in the body the only chance of success is early and total excision with a wide margin of healthy tissue. The proximity and frequent involvement of the ureters and the depth of the wound makes the operation a very formidable one.

Fortunately the cases of nodular infiltrating growths are in the minority. Our figures clearly indicate that the anatomically benign papillary epithelial tumors, whose existence was at one time denied, predominate in numbers over all other forms.

Albarran's much-quoted saying, "En clinique . . . toute tumeur vesicale est maligne ou peut le devenir," is nevertheless strikingly true. There can be little doubt but that any papillary tumor of the bladder, if left alone, will in time cause death either from hemorrhage, obstruction or infection.

In 2 unoperated cases of papillomata found at autopsy at the Massachusetts General Hospital, in which careful sections of the tumors and underlying bladder walls showed not the slightest evidence of malignancy, death resulted from uncontrollable hemorrhage from the bladder. (Autopsy No. 641 and No. 710.)

Examples of malignant degeneration of simple benign papillomata are not uncommon. A case in point reported in my former paper was operated on by Dr. A. T. Cabot at the Massachusetts General Hospital. A small pedunculated papillary tumor was excised from the bladder of a patient who had suffered from intermittent hematuria for three and one-half years. Examination of the specimen showed no evidence of infiltration of the base, the epithelium, except for numerous mitoses, being of quite typical arrangement. The patient was operated one year and six months later for recurrence; at this time the bladder was found filled with a cauliflower growth showing upon examination markedly atypical epithelium and definite infiltration of the base. Death resulted from the disease two months later. Similar cases have been reported by other observers.

Orth has observed near a large unmistakably cancerous papillary growth of the bladder, smaller papillary tumors in which nothing of a cancerous nature could be found. I have already mentioned a similar observation in a case of my own.

Clinical evidence likewise seems to support the theory of malignant transition of originally benign papillomata, for how else are cases to be explained, of which a number have been reported by Fenwick and others, where there have been symptoms of hematuria for twenty years or more, and at operation papillary tumors have been removed, showing but limited epithelial infiltration of their bases? It does not seem reasonable to suppose that such cases could have been malignant from the start, when symptoms have been so mild and the progress of the lesion so slow.

There is a very marked tendency for papillomata to recur. These growths often reappear not upon the original sites, but at other points on the bladder wall, springing up *de novo* as it seems, in response to a general predisposition to the disease which is unaffected by the removal of any one growth. As a rule, rapidly and repeatedly recurring tumors are malignant in the end, if not from the beginning. That every recurrent papillary growth is malignant is far from true, however. In this connection I may cite 2 cases.

In December, 1904, I operated on my first case, and a small benign papilloma was removed through a suprapubic incision and the base cauterized with the actual cautery. In February, 1906, the patient returned with hematuria. No recurrence in the bladder could be seen with the cystoscope; the prostate, however, was regarded with suspicion, and that mildly offending organ was removed by the suprapubic route. Four months later there was again hematuria, and the cystoscope showed the bladder studded everywhere with little papillomata. The case was at that time regarded as hopeless, but it took four terrible years for the patient to die. It was undoubtedly a mistake not to have operated on him again.

Another case was that of a lady fifty-five years old who had profuse hematuria. She had been examined with a cystoscope and told that she had an inoperable growth and that there was no help for her. She finally come into the hands of

[2] Harrington's operation of intraperitoneal cystotomy. Ann. Surg., December, 1908.

Dr. S. J. Mixter in a desperate condition from loss of blood. He did a suprapubic cystotomy and removed eight papillomata from the bladder. Microscopic examination did not show any evidence of infiltration. Four months later hematuria recurred; the cystoscope showed four small growths grouped about the scar of the previous excision. Dr. Mixter again operated by suprapubic cystotomy and removed these growths, which were reported as benign. Three months later the patient, though greatly improved in general condition, again reported hematuria, the cystoscope showed two small growths in the same location, with a suspicious area on the other side of the bladder. In Dr. Mixter's absence, I did the third suprapubic cystotomy, and removed the growths with the actual cautery, searing the suspected mucous membrane on the other side. Two years and six months have elapsed since then, and the patient has been cystoscoped several times, and appears to be in perfect health.

In the light of such experiences as these with papillomata of the bladder, it seems to me our course is clear before us. Until we learn the cause of these growths and can bring about its removal, we must continue to follow our cases relentlessly with the cystoscope, and operate and re-operate as the growths appear.

## THE TRANSPERITONEAL AND SUPRAPUBIC APPROACH TO TUMORS OF THE BLADDER.*

BY CHARLES L. SCUDDER, M.D.,
*Surgeon to the Massachusetts General Hospital; Lecturer on Surgery Harvard Medical School.*

THE most common form of the epithelial tumors of the bladder is the papilloma. In a certain series of 56 operated cases of tumor of the bladder from the Rochester, Minn., Clinic, 42 were of the papilloma type. This affords an idea of the frequency with which papilloma of the bladder is found at the operating table.

There are certain facts of importance which should be considered in deciding upon the operative attack on tumors of the bladder:

1. It is impossible for the pathologist to state with certainty whether or not any given papilloma is malignant without a careful examination of the whole growth, including a section of the bladder wall from which the growth arises.

2. It is even under these ideal conditions oftentimes impossible for the pathologist to determine whether or not a given papilloma is malignant.

3. Practically speaking, all tumors of the bladder cause the death of the patient sooner or later. The supposedly benign papilloma causes death by hemorrhage or pyelonephritis.

4. All so-called benign tumors are potentially malignant. A papilloma which shows no sign of malignancy may become malignant.

5. If the operative deaths and the rapid recurrences of bladder tumors are combined, as Watson has very properly combined them, under the one head of operative failures, these failures have occurred in 29% of the so-called benign tumors and in 46% of the cases of carcinoma.

6. Of the urethral operations for papilloma, only 28% remained cured more than one year.

Of the suprapubic operations, not resections, only 27.5% remained well more than one year.

Of the partial resections, 37.5% remained well more than one year.

7. Of 55 cases of papilloma operated upon through the urethra or suprapubically, or by partial resection, 19 had recurred.

8. The statistics of Nitse in 1901 and 1905 are not corroborated by detailed reports of the cases and consequently should be looked upon as unusually fortunate results.

In view of the above facts pointing to the very great malignancy of papilloma of the bladder, and because of the poor surgical results that hitherto have been obtained by operative treatment, I believe that we should regard, from an operative standpoint, all of the papillomata of the bladder as potentially malignant, and that they should be treated as if they were malignant growths, whether there are evidences of malignancy in any individual case or not.

The approach to the bladder tumor through the suprapubic incision affords, in a certain number of the cases, satisfactory access to the tumor. In a still smaller number of cases the suprapubic approach supplemented by a separation of the bladder from the peritoneum affords easy access to the tumor.

Most bladder tumors are seated at the base of the bladder and in the region of the ureteral openings. For such tumors and for those tumors evidently malignant, I believe that the approach should be by means of the transperitoneal operation of cystotomy. There are certain cases, too, occurring laterally and in the median portion of the bladder that will become more readily accessible through the transperitoneal approach.

The peritoneum is with greater and greater difficulty stripped from off the bladder as one approaches the posterior surface of the bladder low down. Consequently the extraperitoneal suprapubic route is impracticable in many cases. I believe that the transperitoneal approach to the bladder affords the safest means of removing bladder tumors.

The opening of the abdomen enables one to see and palpate the liver, to inspect the peritoneum, the mesentery and the retroperitoneal glands. It is of very great importance that these parts should be inspected before any radical operation is undertaken for the removal of a bladder growth. If metastases are discovered, as they have been several times, a radical operation would be of no use. A sufficient number of cases have not yet been operated upon by the transperitoneal route to establish the mortality percentage, or the percentage of cures and recurrences, but it will not be long before sufficient evidence has accumulated to reply to these inquiries.

The transperitoneal operation enables the surgeon to operate with comparative ease, bloodlessly, aseptically and consequently safely.

* Read before the New England Branch of the American Urological Association, Nov. 29, 1910.

The investigations of Tuffier, De Quervain, Barney and others have demonstrated that normal, sterile urine is not a great irritant to the peritoneum, so that under the very careful precautions taken at a transperitoneal operation there need be no soiling of the peritoneum and adjacent tissues with urine, and this chance of infection may be practically eliminated.

The more I have to do with cancer in any form, whether the supposedly mild squamous-celled epithelioma of the face, or the squamous epithelioma involving the jaw, the more I am impressed by the absolute necessity of a very thorough procedure to eradicate the disease at the outset beyond peradventure of a doubt.

It is far safer, it is far wiser, it is better surgery, to remove the contents of the orbit when the squamous-cell cancer involves the skin near the inner canthus in the immediate neighborhood of the eyeball, even though the eye be intact functionally, than to temporise with an excision of the apparent growth and be forced to a subsequent attack upon the orbital contents when the disease is too far advanced to accomplish more than a palliative operation.

I believe that the same principle holds true in these cases of papilloma of the bladder, *no matter how benign they may appear*. A primary radical excision with the whole thickness of the bladder wall is indicated in the most benign-appearing cases of bladder papilloma.

The improvement of the operating cystoscope, together with the high-frequency current, enables those so inclined to operate upon these growths, and fortunately, and in a way unfortunately, to successfully remove a few. The advent of the cystoscope has made certain the location of the bladder tumors. The employment of the cystoscope for operating purposes seems to me unsurgical in cases of bladder tumors.

It is by the peritoneal route that a safe and comparatively easy access is provided to the bladder.

Regarding the technic of transperitoneal cystotomy:

Rydygier, in 1888, suggested this route to the bladder.

Harrington, in 1893, and Mayo, in 1908, have stated the salient facts in the technic of this procedure. We are all interested in little details which may contribute to a perfecting of this technic. Each operator who undertakes this major but simple exposure of the bladder will modify his procedure according to individual preferences.

I believe that the use of urotropin two or three days previous to a contemplated transperitoneal cystotomy is wise. Preparation of the region of the operation should be as carefully done as for any abdominal section.

If it is known that a *cystitis* is present, the bladder should be thoroughly irrigated before the operation. Tennant, of Colorado, has demonstrated recently that an intraperitoneal cystotomy can be done with safety even in the presence of a severe cystitis. He reports two cases.

The high Trendelenburg position facilitates the operation immensely.

The *abdominal incision* should be an ample one so that the intestine can be displaced upward behind the omentum completely and with ease. The edges of the abdominal wound should be protected by several layers of sterile gauze. I like, personally, to use for this packing off of the intestine a long roll of gauze which is wet and wrung out of hot salt solution.

*If the tumor has been located* by the cystoscope in the upper portion of the bladder, the incision for opening the bladder may be placed so as to approximate to the tumor.

If the tumor is nearer the base of the bladder, then a median opening of the bladder posteriorly will be wise.

The operation may be begun extraperitoneally, suprapubically and, if more ready access to the bladder is needed, the transperitoneal method may be used.

*The urine* is sponged from the bladder as soon as it is opened and the bladder is kept practically dry by occasional gentle sponging. Great gentleness must be observed in handling the bladder. Trauma however slight may be a factor in the recurrence of bladder tumors. Some one has observed that the Trendelenburg position diminishes temporarily the flow of urine from the kidneys.

An excision of the tumor should include the bladder wall. This wound in the bladder wall may be closed by interrupted or continuous suture, or if the wound is not too extensive, the edges and base of the wound may be cauterized with the actual cautery. All hemorrhage should be stopped either through application of the actual cautery or by placing the proper sutures. The suture should be of either plain or chromic catgut.

If the tumor involves the ureteral orifice, this should be excised and the ureter reinserted into the bladder.

*Treatment of the bladder wound.* — The bladder wound may be closed by a continuous Connell stitch of chromic catgut through all the layers similar to the suture used in the closure of the stomach or of the intestine. Or if one chooses, the mucosa and the muscularis may be sutured separately. The peritoneum in either case is approximated separately over the line of the incision in the bladder by a continuous linen suture.

Personally I like to use in wounds of the stomach, intestine or bladder an occasional interrupted stitch to reinforce a continuous suture. I do not often care to trust to a continuous suture alone in suturing any viscus.

If the ureteral orifice is involved and that part of the bladder is resected, or if there appears to be some little oozing of blood, or if the prostate has been removed, it may be wise to permanently drain the bladder either by a suprapubic tube or by a catheter through the urethra. I have used a catheter with the exception of one case in which no drainage was used. I should prefer

to avoid the use of any instrument in the bladder unless it were indicated by one of the three conditions mentioned. Mayo and Judd have only rarely drained the bladder in their transperitoneal cases.

The abdominal wound is closed by layers. If there is a suspicion of any soiling of the wound of the abdominal wall, then a thin small rubber tissue drain had best be introduced between stitches down to the peritoneal layer of sutures.

In conclusion, with regard to the surgical treatment of tumors of the bladder, certain of the small apparently benign papillomata may be safely removed by the suprapubic method, but should be removed even with this approach by a good margin of excised, healthy tissue.

The transperitoneal approach to the bladder will enable the surgeon to successfully attack cases of malignant tumor of the bladder which, without this approach, might be forced to a more dangerous extraperitoneal cystectomy. Watson's proposed cystectomy and double nephrostomy should be employed only when a partial cystectomy done transperitoneally is inapplicable. The transperitoneal approach to the bladder will care for many cases that otherwise would have to be treated by Watson's method of cystectomy.

Transperitoneal cystotomy is a procedure that has come to stay. Its employment should lower the percentage of recurrences in tumors of the bladder of all grades of malignancy.

## PRESENT STATUS OF INTRAVESICAL OPERATIONS FOR TUMORS OF THE BLADDER.*

BY HORACE BINNEY, M.D., BOSTON.

A GLANCE through the medical literature of the last five or six years, bearing on the treatment of bladder tumors, points clearly to at least one fact, namely, that in Northern Europe the intravesical operation has met with increasing popularity. Whereas, at the beginning of the present decade, Nitze and one or two of his pupils seem to have been the only surgeons using this method, the reports in European journals, during the last year, come from at least a dozen surgeons.

In this country, Myer,[1] of San Francisco, and Kolischer and Schmidt,[2] of Chicago, are practically the only surgeons who published evidence of personal experience prior to 1908. Since then a few others have been employing the method, but no publications have appeared except the brief reports of Young,[3] of Baltimore, and Beer,[4] of New York. The increased popularity of the method in Europe, and the fact that in this community the method is employed practically never, seem sufficient reasons for our looking more closely into the question of these intravesical operations.

The development of the intravesical method of operating, which was largely due to Nitze's genius and industry, and the form of instrument used by him, are matters with which every one present is doubtless familiar. I shall, therefore, omit a detailed description of the Nitze instrument, but describe briefly the instruments of a different type which have been recently brought to our notice by other workers in this field. I shall also give a short résumé of the results of reported cases of intravesical operations, as far as known, and shall review the opinions expressed by the more important urological surgeons in the recent French and German urological congresses.

The majority of European intravesical operators and, as far as I know, of American, use the Nitze instrument in its typical form. The chief characteristic of it, namely, the rigidity of the beak supporting the galvanocaustic snare, has been thought a disadvantage by a number of operators, and, therefore, the flexible system, so-called, has arisen. The best known of the flexible system instruments are those of Blum [5] and Kneise.[6] The former has devised a mechanism with a cold wire snare which can be attached to a Nitze double catheterizing cystoscope. The Kneise apparatus is designed for use with Wossidlo's catheterizing cystoscope, and also provides for cauterizing, or injecting solutions into, the base of the tumor. The main feature of these instruments is the placing of the wire loop on the end of a hollow carrier which is introduced through the catheter channel, and can be advanced into the bladder as far as needed, and moved through a considerable arc. This greater freedom of motion than is obtained with the comparatively short and rigid beak of the Nitze allows the cystoscope to be held in one position so that the picture is not constantly shifting. This would appear a decided advantage and is claimed by the authors to greatly simplify the technic.

In contrast with this method, known as the indirect, is the one advocated chiefly by Luys,[7] of Paris, and Keersmæcker,[8] of Antwerp. Luys has developed an instrument resembling an endoscopic tube which is introduced with a beak-shaped obturator. He claims, for its advantages, first, that it is used with air as a medium, thereby avoiding the obscuring of the field with blood; second, that a better view of the tumor is obtained and the cauterization can be more exactly performed, being always in full view of the operator. Keersmæcker's instrument is much similar to Luys', but both of these instruments, having no snare mechanism, necessitate a comparatively large number of sittings for the treatment of anything but the smallest tumor or one with a very small pedicle. It can be easily seen that growths situated on the margin of the internal meatus cannot be reached by the indirect instruments, but must be attacked through a straight tube. Frank [9] reports a number of cases in which he has removed polyps at the bladder neck with an endoscope of his own design. He evidently does not employ it for papillomata within the bladder cavity, as done by Luys and Keersmæcker. While perhaps applicable to the female, it is hard to see how, in the comparatively rigid posterior urethra in the male, these instruments can have a very wide range of usefulness.

* Read before the New England Branch of the American Urological Association, Nov. 29, 1910.

In this country, Myer, of San Francisco, has described a method of operating on tumors in the female bladder. He devised a slender galvanocautery shaft which can be introduced by the side of an ordinary cystoscope and a tumor can be attacked in full view without the necessity of shifting the cystoscope. He claims this to be a simpler and quicker method than with the Nitze instrument, but limited, of course, to the female bladder.

In 1909, Young demonstrated, at the meeting of the American Urological Association, his operating cystoscope, which consists of a two-bladed rongeur through the shaft of which a small straight cystoscope is introduced. A tumor or foreign body, if within reach of its jaws, can be grasped and wholly or partially removed. He has used this in removing recurrent papillomata. Still more recently, a method of attacking tumors was published by Beer, of New York. His instrument consists of a flexible electrode which can be introduced through a catheterising cystoscope and a high-frequency or Oudin current applied to the tumor. Owing to the flexibility of the electrode, the scope of the instrument is large and the technic simple. He has used it in two cases, succeeding in checking hemorrhage and destroying the growth, but his operations are too recent to say whether or not a cure was obtained.

In considering the results of reported cases, we find that Nitze's exceed those of any other operator in number, but in his personal articles he did not prove convincingly that many cases in which he had successfully removed the tumor had been followed long enough to determine a cure. His pupil, Weinrich,[10] in 1905, reported on 170 cases operated by Nitze and himself. Fifty per cent of these cases showed, on cystoscopic examination three years after the removal, no recurrence. Twenty of Nitze's cases had recurred, or 11% of the whole number. There was one death, and in one case suprapubic cystotomy was performed for hemorrhage; result in the remaining cases not known. Other cases are reported by Suarez,[11] one in which two tumors were removed in five sittings; Weinrich,[12] 3 additional cases reported in 1906; Casper,[13] 65 cases with 16 recurrences, in 2 of which he was obliged to perform a suprapubic cystotomy for hemorrhage (he does not give the length of time since operation in cases that have been followed); Asch,[14] 2 cases, 1 of which had no recurrence seven years after operation, second one, operated eight years before by Nitze, in which recurrences appeared at various times, always benign. Boehme [14] reported 5 cases, four papillomata and one fibroma. In these, no recurrence had appeared at the time of publication, excepting one which, after a year, showed a general papillomatous degeneration. Kneise has performed twenty-five operations with his flexible operating attachment, but gives no account of results. Blum reports 4 cases of benign papilloma which he removed in from two to eight sittings. Ringleb [14] has performed twenty-one intravesical operations, once obliged to perform suprapubic cystotomy for hemorrhage, but gives no results. Operations performed by the direct method are few in number, but three reported by Keersmæcker and two by Luys. They claim to have entirely destroyed the tumors, but the period of observation is too short to be convincing of cure.

With the dearth of complete reports of the results of intravesical operations, it is difficult to form any definite opinion of their value, and the question must be still considered an open one, but it is of interest, perhaps, to review the opinions of those who have been most vigorously opposed to it, and to mention some of the advantages claimed by the advocates of the method.

Among the earliest opponents was Israel,[15] who did not believe the operation justifiable on account of the danger of hemorrhage on separation of the scar in the Nitze operations. Rovsing,[14] at the German Congress, in 1909, stated that, since even the smallest papilloma may be malignant, he considered it unwise to use a method which entailed any delay, but advocated the more radical and rapid method of suprapubic cystotomy for practically all cases. Von Frisch,[14] believing that at least 50% of papillomata are malignant, considers the intravesical operation unsafe and is, therefore, opposed to it. Zuckerkandl [14] and Kapsammer [14] are less conservative and advocate its use in very small papillomata which can be wholly removed in two or three sittings. In France, Cathelin,[16] Rafin and others have been opposed to it on the ground of technical difficulties and believe that the operation is less radical than suprapubic cystotomy. On the other hand, the following definite advantages are claimed for it by Weinrich, Casper, Luys, Blum and others: (1) Its mortality is practically nothing (Weinrich, 1 death in 150 cases as compared with 14% mortality from the suprapubic operation, which is the figure published by Von Frisch in his report on 300 cases). (2) The avoidance of complications such as fistula, sepsis, phlebitis or pneumonia, involving long convalescence. (3) The ability of the patient to continue at his work. (4) The more thorough inspection permitted, less danger of overlooking small beginning tumors than in the suprapubic method, in which the bladder is somewhat collapsed and the mucous membrane frequently covered with blood or other fluid. (5) (Important advantage.) The avoidance of danger of implanting tumor cells in other portions of the bladder or in the suprapubic wound which might lead to recurrence. (6) Its greater applicability for recurrent tumors after removal of larger growths by suprapubic cystotomy, it being naturally impossible to subject a patient to repeated operations of such gravity.

In weighing the evidence for and against, one is certainly influenced in favor of the intravesical method, at least in case of smaller growths, by the fact that the most careful and thorough suprapubic excision of small single papillomata is sometimes followed by the development of multiple recurrences, more or less approaching the so-called papillomatous degeneration. A number

of these cases, following suprapubic operation, have been reported by Casper, Lichtenstern,[17] Zuckerkandl and others, whereas this condition seems to develop less frequently after the intravesical operation, one case only being reported by Asch. As stated before, however, details are so scanty and after-results are lacking in the reports of so many operators that no definite opinion can be formed on this point.

The results of these reported intravesical operations, numbering something over 200 cases, may be summarized as follows: Mortality, one half of one per cent, or less, there being but one fatal case in the whole number; hemorrhage, severe enough to require control by suprapubic cystotomy in 3 cases; cure for at least three years has been established by cystoscopic examination in 50% of the cases reported by Weinrich. The exact per cent of cures cannot be figured at present, owing to the failure of the operators to confirm an apparent cure by cystoscope. For this same reason, the frequency of recurrence after the intravesical operation cannot be estimated from the reports. In the original statistics of Nitze, the recurrences are given as 18%, which is better than the figure stated by Rafin in his collected statistics of suprapubic operations, which was 26%.

Inasmuch as Nitze operated on tumors of all sizes, while the tendency at present seems to attack only the smaller benign growths, it is probable that there is a still greater difference in favor of the intravesical operation in per cent of recurrences.

In conclusion, we may say that the published results of intravesical operations do not at present warrant the adoption of the method for the removal of primary growths except in cases of very small tumors or in patients in whom a suprapubic cystotomy under an anesthetic is contra-indicated. In cases of repeated recurrences after suprapubic operations, the method is to be recommended over the performance of frequent suprapubic operations.

My personal experience with the intravesical operation is limited to one case which I shall briefly report.

A man (G. R.) aged sixty-one was operated on by Dr. Cabot in 1906 for a large papilloma on the left wall of the bladder. Recent glycosuria cleared up before operation. Suprapubic cystotomy was done and the tumor cut away from the bladder wall with the actual cautery. Patient made a good recovery, but in the winter of 1908 hematuria returned and a recurrence of the growth was seen with a cystoscope. In March, 1908, second suprapubic cystotomy revealed several large papillomata growths in both lateral and posterior walls of bladder. These were removed as before. Patient was well, without further bleeding, until the spring of 1910, when he had one or two brief attacks of hematuria. On Dr. Cabot's invitation, on June 25, 1910, I cystoscoped the patient, finding a rough, pinkish, oblong mass at the top of the bladder, apparently in the suprapubic scar. I introduced Young's cystoscopic rongeur, under cocaine, and with 4 oz. of boric solution in the bladder was unable to reach the growth, largely, I think, on account of the moderate enlargement of the prostate gland. On my drawing off about half of the solution and pressing down on the suprapubic scar, the growth was grasped in the jaws and a piece amounting to about one third of the whole mass was removed. Separation of the portion caught in the jaws of the instrument was difficult and required a rather vigorous pull before it came away, which was painful. There was moderate bleeding, enough to cloud the medium and prevent further attack on the tumor. There was only slight tingeing of blood in the urine for the next twenty-four hours and no reaction. About ten days later, second attempt was made, which succeeded in removing two small fragments only. On inspecting the bladder wall before attacking the tumor, a couple of small papillomata were seen on the left side of the fundus near the left ureter. Following the operation, the patient went away on a vacation, and was apparently free from bleeding for some time. I had hoped to remove the remaining growths at further sittings, but the patient, in September, had a slight hemiplegia, and soon after, attacks of hematuria recurred, confining him to bed.

Soon after this the glycosuria returned, and uremic symptoms developed. His physician recently informed me that the hemiplegia became complete, and death shortly followed. Towards the end, the hematuria was severe, and injections of resorcin into the bladder were without effect.

## THE EXAMINATION OF THE NOSE AND THROAT IN RELATION TO GENERAL DIAGNOSIS: RESULTS IN ASTHMA FOLLOWING NASAL OPERATION.*

BY H. Z. GIFFIN, M.D.,

*Physician to St. Mary's Hospital of Rochester, Minn.*

IN a consideration of the relation between nose and throat affections and other diseases which are met by the general practitioner, two facts must be kept in mind; first, that the patient's general condition affects the mucous membrane of the nose and throat, and, second, that abnormal nasal conditions affect the general health. It is well known that the nasal mucous membranes are more or less abnormal in every affection which impairs the general health. On the other hand, there are undoubtedly many cases in which the poor general condition is at least in part due to

* This paper is written from the viewpoint of one who is interested principally in medical and surgical diagnosis, and, therefore, is lacks the merit of technicality which might be given by the rhinologist.

unrecognized trouble in the nose and throat. We willingly look upon diseased adenoids and tonsils as harmful, but we do not seem to be so much awake to the fact that other nasal conditions are nearly if not quite as important. Even though prejudice exist in the matter, this should not be an excuse for failure to examine the nose and throat as is often the case. That affections of the nose and throat are not being carefully considered is constantly brought to one's attention. A patient with pronounced nasal symptoms may have visited a dozen physicians, none of whom has examined the nose nor suggested an examination. Meanwhile "catarrh" remedies make fortunes, and the cocaine habit increases. That affections of the nose and throat are credited with an effect out of proportion to their real significance is also true, though this is not done so often by general practitioners.

The specialist who is tempted to jump to the conclusion that nasal disorders can cause everything in all degrees of severity should protect himself by accepting the opinion of those who deal intimately with general treatment. Evidence must be weighed after a general physical examination has been made before deciding upon the significance of any existing nasal condition. The specialist who completes the toilet of his "hundred patients a day" by means of sprays and nebulizers is doubtless filling a popular demand, but he is also a purveyor of mental suggestion in a manner which has little to commend it.

By nasal treatment one would better mean the mechanical removal of diseased parts, or obstructive parts, and the drainage of confined pus; i. e., the removal of polypi or hypertrophied turbinates which obstruct breathing, and the drainage of sinuses; and this for the most part by clean-cut surgery. Treatment doubtless has its place, but should be much restricted.

I shall review in a general way a number of conditions in which nose and throat examinations more particularly suggest themselves, or in which nasal treatment has proved efficacious; and in closing will give some statistics relative to asthma.

The complaints of nasal discharge, of deafness and of nasal obstruction are so often heard and so easily elicited that one would hesitate to consider them were it not for the fact that the physician generally dismisses the matter with a passing remark concerning the frequency of "catarrh," and, strangely enough, the patient seems satisfied. These complaints should be heeded and a careful nasal and aural examination made in order to determine just what may be expected from nasal operation or treatment. Polypi, antrum disease or hypertrophied turbinates may be the cause of the "catarrh."

Acute headaches with fever, no matter to what part of the head the pain may be referred, are often due to sinusitis. The headache is often intense and one may suspect the onset of a severe general infection. Many times when grippe is diagnosed, whether the influenza bacillus is concerned or not, the severe symptoms are relieved upon drainage of an antrum or frontal sinus. Indeed, this is often a more urgent matter than drainage of pus from other parts of the body.

Dull, heavy headaches of a more constant and chronic type, sometimes confined to one side of the head, are quite often due to nasal obstruction or sinusitis. In these cases the turbinates may be hypertrophied or polypoid, and local treatment or operation may be advisable according to the nature of the condition found.

Periodical headaches, or sick headaches, are generally of nervous origin, and nasal operation should be advised only when more serious nasal trouble is found. Something can be learned from examination of the nose during an attack. Even in this type of headache, however, considerable relief, particularly in the severity of the attacks, follows operation in properly selected cases. Indeed, we believe examination of the nose and throat in the various forms of headache to be more important than the examination of the eyes; yet in most of our cases the eye condition has been previously corrected, while the nose and throat have been almost entirely overlooked.

The association of headache or nasal obstruction with the onset of the patient's complaint, particularly if the complaint be a periodical one, makes us suspect nasal disorder. This is observed in several conditions. Asthma, epilepsy, dizziness and various stomach and digestive disorders of a milder type are frequently associated with headache. The headache is generally the resultant, in these cases, but occasionally it would seem to be the antecedent, and if so one must consider the possibility of nasal influence. Especially have we seen benefit from operation when there is a complaint of morning nausea and vomiting associated with headache, if the patient does not impress one as being markedly neurotic. Many patients complaining of dizziness associated with nasal obstruction or headache have been relieved. The epileptic should have the same careful examination that is required in cases of headache, including the eye, nose and throat. One does not expect cure of epilepsy to follow operation, but frequently improvement has been observed. Cases certainly should not be operated upon unless decided trouble is found.

The effect of chronic fibroid tonsils upon the recurrence of articular rheumatism and other diseases of the rheumatic cycle should be considered. Cases of chorea will often improve more rapidly after tonsillectomy.

The relation of tonsillitis and sinusitis to the more chronic types of arthritis is indefinite and requires more study.

More particularly must one emphasize the importance of a careful search for all possible causes of severe anemia. Anemia of itself will cause intumescent turbinates and an edematous condition of the nasal mucous membranes. This must be interpreted as secondary. But, on the other hand, an antrum full of pus will make it difficult to improve the blood. I have seen anemics improve rapidly after drainage of an antrum when placed upon the very treatment which had formerly failed.

Patients with facial neuralgia have been operated upon several times before an antrum full of pus was discovered, the pain promptly disappearing after proper drainage.

Tumors of the face and neck, including goiter, should have nose and throat examinations for diagnostic purposes. A few glands high up near the angle of the jaw, even if they are quite large, may disappear rapidly after tonsillectomy. With tuberculous glands of the neck, the tonsils are usually in bad condition, and sometimes it seems best to remove them. In goiter, paralysis of a cord may be present even though no hoarseness exists, and if this be not discovered before thyroidectomy, the surgeon is unjustly blamed. One occasionally sees a cyst in which malignancy has been suspected correctly diagnosed as abscess of the antrum by means of nasal examination. Tumors of quite similar characteristics are found upon nasal examination to be sarcomata of the antrum. Cases long treated as ulcerated tooth prove to be abscess of the antrum.

It need hardly be mentioned that mediastinal growths and thoracic aneurysm often cause paralysis of a vocal cord, generally the left, occasionally the right, and that the patient is sometimes referred from the nose and throat department for general examination. It is not so well-recognized, however, that an apical lesion of the lung may cause paralysis of the right vocal cord.

It is well to know the nose and throat findings where lues is suspected. The diagnosis is often very easily confirmed in this way and occasionally a doubtful case is entirely cleared up. A luetic perforation of the bony septum is easily overlooked. One must be careful, however, not to diagnose every perforation of the septum as syphilitic. Some are traumatic, others trophic or tuberculous, but these are generally perforations of the cartilage.

Irritative cough, especially night cough, may be entirely a reflex matter, and sinusitis may be found. This leads directly to a consideration of certain forms of asthma which are apparently influenced by nasal conditions. Our experience with nasal asthma has been moderately encouraging. Every asthmatic is referred to the nose and throat department in the course of routine examination, and selected cases are operated upon; that is, cases which show polypoid growths, sinusitis or hypertrophied turbinates, which clearly cause nasal obstruction.

During the year 1909, 66 cases of asthma were operated upon by Dr. Justus Matthews, in the clinic of St. Mary's Hospital. In 35 cases turbinectomy was done; in 26 of these, double middle turbinectomy; in 10, one or both inferior turbinates were also resected. This was the operation of greatest frequency. In 12 cases polyps were removed. In 9 one or both antrums were drained, and in 6, deformities of the septum were corrected. Four cases were in children, and adenoids and tonsils were removed.

In the general examination of these patients there did not appear to be any distinction between the different types of nasal affection discoverable in the symptoms, or signs of the asthma. After operation the patients were placed upon small doses of iodide for two or three weeks, as is customary after nasal operations.

Reports have been received from 52 cases, nine months to one and one-half years after operation. Two have since died of unrelated affections. Two are worse than before operation; the attacks are more frequent and more severe and the general health is worse. Thirteen can see no definite change in their condition. The frequency of attacks may be diminished and the severity increased, or vice versa, but they cannot report themselves as better or worse. Thirty are definitely much improved, both as to frequency and severity of attacks, and in their general condition. Five consider themselves cured, which, of course, only means that they have had no attacks since operation. One of these patients had had asthma for twenty years, another for sixteen years.

In other words: Definite improvement has followed in 57%, and "cure" in about 10%.

On tabulating the results, one finds that, in general, when the attacks become less frequent, they also become less severe. The general health had improved in 33 of the 52 patients. Headache had been a symptom in 31 cases and had improved in 24. Mild stomach symptoms were elicited in 25, and had improved in 20.

Of the operations upon the 5 patients who were "cured," 4 were turbinectomies, and 1 the removal of polyps.

Improvement followed in 3 of the 4 cases in children in which adenoids and tonsils were removed.

The most unusual things will occasionally cure asthma. Looking upon the condition as a spasmodic neurosis, one would, however, expect strange cures. In reality one should not strive for cures only, but should be satisfied with any procedure which will cause improvement in the majority of cases. Nasal operation seems to do this if the patients are properly selected. And there would seem to be good logic in freeing the respiratory tract of anything which might cause reflex irritation.

In conclusion, it may be reiterated that examination of the nose and throat for diagnostic and therapeutic purposes should not be neglected. On the other hand, these are not parts of the anatomy to be needlessly tampered with simply because they are accessible. Like the gynecologist, the nose and throat man may court distrust by overenthusiastic specialization.

active infecting agent is deposited in the tissues about the tubercular focus. If, then, the process goes on so rapidly that there is great destruction of tissue and discharge of pus and detritus, there may be so rapid a removal of the tubercle bacilli that they appear profusely in the urine for a while and then more rarely until they escape only when an occasional focus breaks down. A sediment injected at a time when there are free bacilli should and probably will produce tuberculosis in a guinea pig, but there may be times when a tubercular kidney will secrete urine free of bacilli. There is then no constant stream of bacilli flowing out of a tubercular kidney, and while the presence of tubercle bacilli in the properly obtained sediment proves their source to be in the urinary tract, their absence proves nothing so far as diagnosis goes.

Dr. W. F. Whitney: I remember a case similar to Dr. Tenney's a year ago. Many examinations of the urine were made, all with negative results, and then later great quantities of tubercle bacilli appeared.

### A case of double renal calculus. Nephrectomy. Recovery.

Dr. F. B. Lund: This case is shown on account of the interest attached to the clinical problem of the removal of very extensive calculi in one kidney at the halves of the kidney were united by deep catgut sutures around a large rubber tube which was passed through the wound into the pelvis of the kidney and brought out of the external wound. The bleeding having entirely stopped, the kidney was replaced and the external wound drained. The patient was in good condition at the close of the operation, at about ten in the morning. At twelve, it was noticed that the dressing was stained with blood and the patient's pulse had risen from 80 to 100. At three in the afternoon, his pulse was 120. The patient was restless, sweating and pale and the dressing badly soaked with blood. It was then seen the nephrectomy must be done in order to stop the hemorrhage, and the

### DEMONSTRATION OF SPECIMENS.

#### SPECIMENS OF TUBERCULOSIS OF THE KIDNEY, IN WHICH GUINEA-PIG TEST WAS NEGATIVE.

DR. B. TENNEY, Boston: Within a short time I have done three nephrectomies for pain, with pus and blood in the urine and frequent and painful urination. The symptoms of disease had been present in these patients for four, six and three years. One had had his appendix removed and a cystotomy with drainage for three months before his nephrectomy. Both of the others had lost ovaries, tubes and appendices. In every case the urinary sediments had been injected into guinea pigs, — twice with one patient, — and the autopsy findings on the pigs after six weeks were negative. The examinations were all made at the municipal laboratory, where the rule is to inject two pigs at a time and never to autopsy before six weeks.

Two of the removed kidneys were examined at the Harvard Pathological Laboratory and the other at Tufts. The diagnosis returned to me was tuberculosis in each case.

Without thinking much about it, I had assumed that the negative answer from the guinea-pig test was evidence against the diagnosis of tubercular kidney. Here are three cases where it was worthless. Two years ago I had another surprise. Here is a color drawing of a hydro-pyo-nephrosis in a rabbit, which was produced by an injection of a suspension of tubercle bacilli which were obtained in pure culture from Prof. Theobald Smith and injected into the renal artery of the rabbit. The culture was three years old and was fatal to guinea pigs. The rabbit died ten months after the injection and the kidneys and bladder were removed and turned over to Dr. E. H. Nichols for microscopic examination. He could find no trace of a tubercular process anywhere in the little remaining kidney tissue, the wall of the sac or the ureter, and yet I know that the process started with a tubercular infection ten months before death.

The only explanation which appears reasonable and adequate is that some other infective agent, more active than the tubercle bacillus, came in, producing more active destruction of tissue, and that the more active process overgrew and destroyed or removed the tubercle bacilli and the evidence of their previous occupation.

It is reasonable to suppose that the same thing may occur in the human kidney. A deposit of tubercle bacilli may occur and extend but slowly until a more active infecting agent is deposited in the tissues about the tubercular focus. If, then, the process goes on so rapidly that there is great destruction of tissue and discharge of pus and detritus, there may be so rapid a removal of the tubercle bacilli that they appear profusely in the urine for a while and then more rarely until they escape only when an occasional focus breaks down. A sediment injected at a time when there are free bacilli should and probably will produce tuberculosis in a guinea pig, but there may be times when a tubercular kidney will secrete urine free of bacilli. There is then no constant stream of bacilli flowing out of a tubercular kidney, and while the presence of tubercle bacilli in the properly obtained sediment proves their source to be in the urinary tract, their absence proves nothing so far as diagnosis goes.

DR. W. F. WHITNEY: I remember a case similar to Dr. Tenney's a year ago. Many examinations of the urine were made, all with negative results, and then later great quantities of tubercle bacilli appeared.

#### A CASE OF DOUBLE RENAL CALCULUS. NEPHRECTOMY. RECOVERY.

DR. F. B. LUND: This case is shown on account of the interest attached to the clinical problem of the removal of very extensive calculi in one kidney at the time when there is a calculus probably in the ureter on the opposite side.

The patient, a man of thirty-seven, was well until six weeks before I saw him and actively engaged in his employment as shipper in a large mill. Six weeks ago he was standing on the front platform of an electric car when the car was struck from behind so that a brass rail on the car gave him a blow on the left side of his back. Then he began to suffer from severe headaches and to pass bloody urine. He called on his physician, Dr. Hartwell, of Norwood, who found clear, fresh blood in his urine. He was given urotropin but continued at his employment. The blood gradually disappeared from his urine and one week ago his headaches and backaches had left him. Three days before I saw him, in the afternoon, he was attacked with severe pain in the right side extending down into the right testicle. Yesterday he had a typical attack of renal colic. He was doubled up with pain requiring morphia. Blood had reappeared in his urine. Examination showed a well-developed, well-nourished man, rather pale; no swelling or tenderness could be felt in either loin. The x-rays were then taken by Dr. Percy Brown and they are reproduced here. As you see, there is shown a very extensive calculus formation in the right kidney, and a small calculus apparently in the left ureter. A careful attempt was made by a skilled operator to catheterize the ureters, which was not successful owing, apparently, to the swelling and edema about the ureteral orifices. It was thought absolutely essential to remove the stones in the left kidney, and it was determined, if possible, not to remove the kidney itself on account of the doubt whether the right kidney was capable of carrying on sufficient urinary excretion, especially since it seemed probable that there was a stone in the right ureter. On July 25, I cut down on the left kidney through a lumbar incision. The kidney was found considerably enlarged and lobulated, there was a soft spot near the upper pole, and it was found to be filled throughout with a great, branching stone. The kidney substance was thin at the upper pole and was there incised, allowing the escape of purulent urine. In order to get out the branching stone, it was necessary to completely bisect the kidney. The bleeding was controlled by tension on the vessels and by pressure with the fingers of an assistant. After removing the stone, the two halves of the kidney were united by deep catgut sutures around a large rubber tube which was passed through the wound into the pelvis of the kidney and brought out of the external wound. The bleeding having entirely stopped, the kidney was replaced and the external wound drained. The patient was in good condition at the close of the operation, at about ten in the morning. At twelve, it was noticed that the dressing was stained with blood and the patient's pulse had risen from 80 to 100. At three in the afternoon, his pulse was 120. The patient was restless, sweating and pale and the dressing badly soaked with blood. It was then seen the nephrectomy must be done in order to stop the hemorrhage, and the

kidney which you see here was removed. It was considerably dilated and thinned out in places, but contained a good deal of healthy kidney tissue. The other kidney immediately took up the double burden and the amount of urine was sufficient almost from the first. There has been no blood in the urine and no attacks of calculus colic on the right side. The patient has gained markedly in health and strength, he is hard at work and says he feels better than ever before in his life. An x-ray would be interesting so as to see whether the stone seen on the other side is still present, but owing to the man's condition and the absence of blood in the urine it seems probable that this stone has at some time been passed. I think it is much safer to remove a kidney so greatly affected by calculus disease as was the left kidney in this case, under ordinary circumstances. The risk of leaving it after splitting it and sewing it together was taken, in this case, however, on account of the danger that the other kidney might not be adequate to the double burden. When nephrectomy became compulsory it was gratifying that such proved to be the case.

In regard to the source of the hemorrhage, it may be stated that the deep sutures of catgut passed through the pelvis of the kidney and tied around its outer border, thus radiating from the pelvis as a center. No quilt sutures were passed as it was thought there might be a possibility of causing necrosis of the kidney tissue by tying too tightly and the deep sutures apparently completely controlled the hemorrhage. After replacing the kidney in the loin it was observed, for about two minutes, that the hemorrhage had apparently stopped, so that it seems as if it could hardly be due to the relaxation of the tension in the vessels, occasioned by putting back the kidney. The weight of the calculi, which proved to consist of one very large branching calculus and one small, spheroidal calculus, was 710 gr.

### UNILATERAL KIDNEY.

DR. J. D. BARNEY: I wish to show you to-night a good specimen of congenital unilateral kidney. I am enabled to do this through the courtesy of Dr. Magrath, our medical examiner, who removed the specimen in a medico-legal autopsy.

I will read Dr. Magrath's description of this specimen.

Kidneys: The left seemingly absent; the left adrenal gland in normal position, 6 x 3 cm.

Section of aorta shows right renal artery in normal position, with absence of the left. Just below the orifice of the inferior mesenteric artery are two small openings, evidently those of the left adrenal arteries. The inferior vena cava shows a single renal vein, that of the right side. The left spermatic vein runs upwards to the adrenal gland, apparently anastomosing with veins from the gland.

On careful dissection no left ureter is demonstrable; the right ureter is in normal position.

Right kidney in normal position, likewise the right adrenal gland; estimated weight of kidney, 200 gm.; length, 13.5; breadth, 7; thickness, 4.5 cm. Surface smooth, brownish-red. Upon section color is similar throughout. Cortex, 0.9 cm. thick. Markings and consistence normal.

Bladder practically empty, mucosa somewhat injected. Right ureteral orifice easily demonstrable, the left not apparent.

External genitalia normal.

If any one is interested, I will refer them to the article on this subject by Dr. J. M. Anders, of Philadelphia, published in the *American Journal of Medical Sciences* in March, 1910. I have made the following notes from it. Out of a grand total of 92,690 autopsies, the ratio of unilateral kidney is 1 in 1,817. Two hundred and eighty-six cases have been reported to date. It occurs more frequently in Wales. The age at time of death is of interest, as showing how little life may be affected by this condition. Thirty-four died under ten years of age, 62 died from the tenth to the fiftieth year, 58 died after the fiftieth year, 2 died after the eightieth year. The left kidney is more often absent than the right, but when sex is considered it is found that the right side is more often absent in women than in men. In practically every case the ureter is entirely absent, but in a few it may be rudimentary. The adrenal gland is usually present on the side of the absent kidney. In a large per cent of cases the external genitalia show some congenital defect.

Unilateral kidneys have often been operated on, and not infrequently removed. With our modern methods of cystoscopic examination such a catastrophe is bound to be a rarity, to say the least, but there are emergency cases (ruptured kidney, for instance) where no time or means are at hand to ascertain the conditions, and where the surgeon has no choice but that of operative interference.

### DISCUSSION.

DR. P. THORNDIKE: I also wish to be known as one of the twenty-seven men who have taken out a single kidney. Some time ago I found on the accident table at the City Hospital a man bleeding to death from a ruptured kidney. He was exsanguinated. He had a bladder full of blood and a blood tumor in his loin. He had fallen into the hold of a ship and ruptured his kidney. It was an acute surgical emergency. I made a loin incision and took out the crushed and battered fragments of what was once a kidney. The man died shortly after and at the autopsy it proved that this was the only kidney that the patient had. In this case the operation was imperative to save life. There was no time for cystoscopy or further examination, and no good could have come from them had they been attempted.

DR. F. S. WATSON: I think Dr. Barney has understated the number of cases of single kidney that have been operated on. I may be wrong; I hope so, because I have done it myself and know of a surgeon who has had a similar misfortune.

DR. L. DAVIS: I had a case last summer at the Massachusetts General Hospital, supposed to be an acute appendix. A woman was admitted through the accident room with a large mass in the right flank, which was moderately tender; she had fever and pain. I thought it was an acute infection of the kidney, and cut down on it without preliminary cystoscopy, as the patient seemed acutely sick. I found a big tumor of the kidney like a hypernephroma. Passing the hand into the peritoneal cavity, I could feel no kidney on the other side. There was nothing to do but back out and sew up the wound. A subsequent cystoscopic examination showed absence of a ureteral opening upon the left side. The patient has failed rapidly since operation, and I think there is no question but that it is a case of malignant disease of a solitary kidney.

### DIVERTICULUM OF THE BLADDER REMOVED AT OPERATION.

DR. A. L. CHUTE: I showed at one of our meetings last spring a radiograph of a ureter catheter with a metal stylet coiled up in a diverticulum of the bladder. I now have the excised diverticulum to show you.

This man, age thirty-four, was referred to me by Drs. Whitney and Pearce. He had had several attacks of gonorrhea. His urine had been very turbid for a year and a half and he had had at times discomfort on

urination. Bladder washings and vaccines made from his own strain of colon bacilli had given no relief.

Bladder examination showed a diverticular opening about the size of an ordinary fountain pen barrel near the left ureter. He had a residual of 5½ oz. His reflexes were normal, as was his prostate. On Oct. 5 a ureter catheter was passed into his left ureter, to serve as a guide, and his bladder washed and distended with air. An incision was made through his left rectus muscle and carried down into the perivesical connective tissue. The peritoneum was pushed backward from the bladder and diverticulum. The latter showed as a small sac just to the left of the bladder.

The dissection was carried on with a good deal of difficulty until the diverticulum had been everywhere separated except at its point of communication with the bladder. The sac was difficult to separate at its neck and had to be opened before this could be done. I tied off the sac, cut it, and brought the muscular coats of the bladder together over the stump with two layers of sutures. I used a large drainage tube and wicks brought out at the lower angle of the wound. The loose connective tissue about the bladder suppurated very freely, but there was no leakage of urine at any time. The convalescence would, I believe, have been shorter if I had drained through the perineum as Von Eberts did in his case.[1] The ureter catheter was a great help in closing the opening in the bladder, which was very near the ureter.

The specimen I show you has been "reconstructed" in a way, in that it has been distended with gauze and sewed up. It is less large than it looked *in situ*. It is probably of the acquired type as its walls were made up of mucous membrane and a layer of friable fat. The opening into the bladder was in a higher level than the base of the diverticulum, which rested on the muscular diaphragm of the pelvis.

The patient has now reached the stage where his urine is clear for several days at a time, and then becomes a little turbid. He does not quite empty his bladder, having a residual of about an ounce. Whether this residual is due to faulty contraction of the bladder, due to adhesions following operation, or to a small bar at the outlet is not evident. The patient shows normal reflexes.

*Radiographs of a dilated kidney pelvis.* — Here are two radiographs, taken by Dr. Percy Brown, of a renal pelvis filled with 10% collargol solution. They show very well the dilated pelvis and calyces and also the sagging of the kidney when the patient stood. The patient, a woman of thirty-nine, had a marked enteroptosis. A year ago she had her uterus fixed to the abdominal wall. She then began to have attacks of severe pain that began in her right loin and radiated to her bladder. They would be followed by the passage of a large amount of clear urine. Catheterisation of her right renal pelvis showed a residual of 17 ccm. of clear urine. If distention of her pelvis was carried beyond 30 ccm., it started the same sort of pain that she had during her attacks. It seemed probable that her movable right kidney caused at times overdistention of the kidney pelvis and the attacks of pain.

Her kidney was exposed and freed; the ureter joined the kidney pelvis normally, but was twisted and curved below the kidney. The ureter showed no other abnormality. The kidney was fixed in place and some months later catheterization of the kidney pelvis showed no residual. For a time this patient was free from pain; now she complains of severe pain in the gall-bladder region. Such attacks of kidney pain as I saw seemed real.

[1] Ann. Surg., 1909, vol. l, p. 823.

HYPERNEPHROMA.

Dr. P. Thorndike: I wish to show this specimen, which is the half of a right kidney, the greater part of which has been invaded by a hypernephroma. It came from the one patient upon whom I have ever operated for bleeding so severe as to be an acute surgical emergency. I saw the patient late in his disease. He was bleeding so fast that his bladder was constantly full of blood, which he was straining to pass, and there was a tumor of blood in his loin. Immediate nephrectomy was done. The substance shows that almost the whole of the kidney substance has been replaced by the diseased tissue.

Dr. Lincoln Davis read a paper entitled

SOME CLINICO-PATHOLOGICAL DATA ON BLADDER TUMORS.[1]

Dr. C. L. Scudder read a paper entitled

THE TRANSPERITONEAL AND SUPRAPUBIC APPROACH TO TUMORS OF THE BLADDER.[2]

Dr. Horace Binney read a paper entitled

THE PRESENT STATUS OF INTRAVESICAL OPERATIONS FOR TUMORS OF THE BLADDER.[3]

DISCUSSION.

Dr. W. F. Whitney: In regard to the pathology and prognosis of tumors of the bladder. While any form of tumor that occurs in other parts of the body may occur here, the papilloma and cancer are by far the most important and frequent.

It is strange that papillomata should develop from a mucous surface which normally is without papillæ. But such is the fact, and these fibro-epithelial growths probably start from small vessels which push out above the surface and carry with them the fibrous tissue and epithelial covering. These keep pace with their subsequent growth and branching. If this is all, there is finally formed a branching villous growth connected by a thin stalk with the bladder wall. These are essentially benign, although often multiple, and their removal is not followed by recurrence.

But this process is not always so simple, for with the outgrowth there is frequently a tendency for the epithelium to grow into the submucous tissue to a varying extent. With this comes the tendency to recur, and then the name of a villous cancer becomes justified. Unfortunately for the differential diagnosis, simple inspection or even microscopic examination of the relatively easily accessible villous part does not enable one to be made always. Although the thickness of the epithelial layers, and the abundance of mitotic figures, may make one suspicious, the true nature only can be determined surely after examination of the base. Here, besides solid epithelial columns, there are found sometimes hollow tube-like structures lined with epithelium recalling tubular glands. These have been regarded as arising from included epithelium from the interstitial tract during development. There is little tendency for these tumors to generalise, and they extend, locally invading the surrounding tissues and near lymph nodes. Upon this is based the hope of relief that may be expected to follow a radical operation, unfortunately limited by the anatomical relations.

Besides these, there are cancers which start as such at the beginning without any outgrowth, but begin to infiltrate from the very commencement. The male sex over fifty are most frequently the victims of such growths.

[1] See Journal, page 222.
[2] See Journal, page 224.
[3] See Journal, page 226.

I wish to show the specimen of cystic growth having its origin in the prostate mentioned by Dr. Davis in his paper.

It was an oval growth the size of an egg. On section, it showed numerous cysts of varying size. The structure was that of the prostatic gland in which the acini had increased and dilated to form the cysts. Just beneath the surface, in one part, there was a serous infiltration of the subepithelial tissue with extension between the epithelial cells, forming between them small cystic cavities. This latter condition is a very unusual one.

DR. F. S. WATSON: In the surgical treatment of cancer there is little, if any, disagreement with respect to the following things:

1. If cure or lasting results are sought, it is futile to employ any surgical procedure which does not remove or destroy all the tissues invaded by the disease.

2. In a few examples of the disease, of which cancer of the lip is one, this may be accomplished by means of an operation of relatively slight extent and gravity; in the great majority this is not the case, and we are obliged to employ very radical and extensive measures if we would gain our end.

3. When the disease has its seat in some organ of the body, experience has taught us that even when but a small part of the organ is involved in the process we must nevertheless remove the whole organ and oftentimes more or less of the adjacent structures as well, if we would provide the best protection against recurrence, and that we do not secure this if we limit our operation to the removal of the tumor itself or to a part of the organ only.

4. That the one golden opportunity to obtain cure in cases of cancer is by performing a most thorough and radical operation at an early stage of the development of the disease.

5. That it is not reasonable or proper to apply radical procedures in cases in which such measures cannot offer a reasonable chance of removing all the tissues invaded by the disease, or when the danger to life is very great, or when if the patient survives he is left with a very distressing infirmity or is disabled.

Now the question is, Is vesical carcinoma an example of the disease in which we can hope to prevent recurrence by means of an operation of relatively slight extent and gravity, as we may in cases of cancer of the lip, or is it one to which we must apply the most radical measure that is justifiable if we would secure that end? That is to say, shall we best protect the patient against recurrence by employing excision of the tumor, by partial resection of the bladder or by total cystectomy? The whole history of the surgical treatment of vesical carcinoma forces us to the conclusion, as it seems to me, that the only logical road to follow when seeking cure in these cases is by the application of total cystectomy, for nowhere more than in the bladder does carcinoma show the tendency to recurrence, and it has been one of the most discouraging chapters in the history of the surgical treatment of cancer.

In view of this record of failure, in view of the fact that the disease is slow of development in some cases, and in view of the further fact that a comparative degree of comfort can be secured for a good many of the patients by the employment of palliative surgical methods, many surgeons are tempted to give up the effort to obtain cure by radical operations and advocate the use of the palliative ones only, no matter in what stage of development the tumor may be.

This position is not altogether unreasonable, and there is something to be said in favor of it, but it does not seem to me to be a sound one to take until we have exhausted our resources in seeking cure, and I do not think we have arrived at that point yet. I say this because I do not think we have hitherto given the operation of total cystectomy a fair chance to show what it can accomplish by way of obtaining cure. With but few exceptions it has been practiced in the worst cases only; those in which the tumor was extensive and when the patients have been much enfeebled and are not in a condition to withstand the performance of so grave a procedure. In some instances it has been done when the disease had already exceeded the limits of the bladder and when, therefore, it was improper to have applied any radical measure at all; finally, it has until very recently been carried out in a manner which invited disaster and failure.

While these things have been true of total cystectomy, quite the contrary has been the case with respect to the operations of excision and of partial resection, both of which have been employed under far more favorable conditions in far the larger number of cases. Total cystectomy, then, has been shown at its worst, the other two measures at their best. We cannot, therefore, look for any important gain in the results of these, while we have, I believe, good reason for anticipating much better ones from total cystectomy.

The objections to that operation have been, of course, the immense mortality attending it and the distress which it involved to those who survived it, owing to the existence of a permanent urinary fistula or to the emptying of the urine into the vagina or the bowel.

Now if we could greatly lessen the mortality of this procedure and so dispose of the urinary drainage as to not merely secure the comfort of the patient, but allow him to lead an active life, we should at once place total cystectomy among the practical operations, and it would not only become much more frequently employed, but would be, as I have said, the only logical road to follow when seeking to obtain cure in cases of vesical carcinoma.

In the December number of the *Annals of Surgery*, 1905, I presented a plan by which I believed these ends could be secured and the grave objections to total cystectomy overcome. In the course of that communication I showed that the great mortality of the operation was due to two things: Shock, and renal infection. I showed, furthermore, that the deaths from renal infection were due in most instances to ureteral implantation which invited it, and I stated it as my belief that the deaths from shock were due to the fact that the diverting of the urinary secretion was carried out at the same time that the bladder was removed, thereby greatly prolonging that part of the operation and making it a difficult and trying procedure and one of great severity.

The plan by which I proposed to overcome these difficulties and objections to the operation was as follows: (1) To abandon ureteral implantation altogether, and in its place to substitute simultaneously performed bilateral nephrostomy, tying off the ureters high up and establishing renal fistulæ in the loins. (2) That this operation should be done as a step preliminary to the removal of the bladder. (3) When the patient should have recovered from the nephrostomies, to remove the bladder and its adnexa, which then would become a relatively simple and rapidly performed operation because of having the necessity of diverting the urinary secretion eliminated from it and attended to beforehand.

By this means I believed that the deaths from shock would be greatly lessened, and by the same means I felt sure that those arising from renal infection would become greatly decreased, as we know that nephrostomy and continuous drainage if properly arranged and properly cared for does not invite infection of the kidneys

and that when infection did occur, its consequences were rarely of serious import to the patient.

I confidently predicted that if this plan were applied when the tumor was in an early stage of development, we should obtain a very considerable number of cures or lasting results.

The essential features of the plan were then as follows: Reducing of shock and averting of renal infection by one and the same step, namely, preliminary bilateral nephrostomy, tying off the ureters and establishing permanent renal fistula in each loin.

There remained to be dealt with the second objection, namely, the distress to the patient arising from the existence of a permanent renal fistula. This I overcame by devising an apparatus for disposing of the drainage and leakage of urine, by means of which the patient is kept dry, free from odor and perfectly comfortable, and is thus enabled to lead an active life.

I have a patient who has had a renal fistula in one loin for sixteen years and one in both loins for the past seven years. Throughout this time he has been in good health, perfectly comfortable, and actively engaged in a business that requires him to mingle freely with people, none of whom are aware of his infirmity owing to the fact that he is not soiled with urine and his clothes are kept dry and free from odor. This one case is a refutation of the oft-repeated phrase that the distress necessarily connected with permanent urinary fistula in the loin is so intolerable to the patient that he may well prefer death to enduring its miseries. That statement is true only for the patient of the surgeon who does not know how to arrange for the disposal of the drainage and leakage of urine in such a way as to secure for him comfort and the ability to lead an active life such as I have given to the one to whom I have referred.

I am happy to say that this plan which I proposed six years ago has appealed to some of my colleagues and has either received their endorsement or been adopted by them. These gentlemen are the distinguished president of our first Congress in Paris, Albarran; his brilliant young associate, Heitz-Boyer, and Brongersma, in Europe; in America, my much-esteemed colleague, the late Tilden Browne; my fellow townsman, Hugh Cabot; while its essential feature, namely, the preliminary diverting of the urine, has been put in practice by Bottomley, of Boston, and our eminent president of this congress, Fenwick, though the two last-named gentlemen have preferred to employ ureterostomy for the purpose instead of the double nephrostomy which I advised.

In conclusion, I wish to say a few words with regard to the treatment of the benign tumors.

The following things have been established with respect to this class of tumor:

(1) Nearly two thirds of all vesical tumors are malignant. (2) There is an extraordinarily marked tendency to recurrence after the removal of such tumors. (3) In some cases this recurrence is in the form of multiple tumors; in some it has been in the form of a malignant tumor *in situ*, and in a few it has been in the form of another benign neoplasm. (4) As many as nine years have elapsed after the removal of a benign tumor and the appearance *in situ* of a malignant one. (5) Single papillomata having well-marked stems, and a relatively small base, if found to be of benign structure after removal, upon examination of all its parts, do not as a rule recur. In some instances also of broad-based sessile tumors of benign nature recurrence does not take place, though in a larger number of them it does occur. I have one patient from whose bladder I removed by excision such a growth having a base as large as a crown piece twenty years ago who has never had the slightest evidence of recurrence.

In view of the facts just stated, it seems to me that we should treat cases of recurrent tumors following the removal of benign ones *in situ* in the same way that we should treat malignant tumors at the outset, unless we have very good reason to feel sure that the recurrent tumor is also benign.

For benign tumors in the first instance, the endovesical methods may be employed fitly, but I cannot see wherein they are more likely to be productive of lasting results than an operation which removes the tumor more completely than in the nature of things can be done by them. I would, therefore, reserve the endovesical method for the small single benign neoplasms having well-marked stems and would apply to all other benign tumors of the bladder the intraperitoneal method of excision proposed and performed by Harrington, of Boston, and by Rydygier, and recently revived by the Mayos, of Rochester.

Dr. C. L. Scudder: I should like to say one word regarding Dr. Watson's attitude toward total cystectomy for evident malignant disease of the bladder.

It seems to me that it is a most reasonable view that if malignant disease exists in some part of the bladder, this disease may be removed without removing the whole bladder. Dr. Watson, as I understand him, would substitute for partial cystectomy a total cystectomy with a nephrostomy.

I believe that there is a large number of cases of carcinoma of the bladder in which the disease is so localized in some part of the bladder wall that it is possible to excise or resect the disease safely and retain a portion of the bladder *in situ*. The perfection in the technic of the transperitoneal approach to the bladder has rendered the operation of partial cystectomy a safe and effective procedure. I believe that the Rydygier-Harrington transperitoneal approach to the bladder will take from the group of cases to which a total cystectomy formerly was applicable many cases for a partial cystectomy.

Dr. Hugh Cabot: The tendency of this discussion has been to lay stress upon the seriousness of the condition and the unfavorable prognosis. In looking over the statistics of foreign observers I find that their experience is by no means so unfavorable. Thus Zuckerkandl reports that in the last six and one-half years he has had 72% without recurrence. Bosch reports 31 cases, of which 12 were benign, 15 malignant and 4 doubtful. Of the benign cases 1 was operated upon by the endovesical method, 2 were not operated upon and were well respectively sixteen and seven years later. Of the 9 cases operated upon, 7 were followed, and of these 4 were without recurrence. Of the malignant and doubtful cases, 12 were operated upon. Of those not operated upon, 5 died, respectively one-half, four and one-half, three, three and fifteen years after operation. One is still alive three years later. Of the patients operated upon, 3 died as a result of the operation. The remaining 6 died respectively six, two, fifteen, fifteen, ten and five years after operation. Three are still alive after eighteen, fourteen and nine years. This is certainly a much better showing than we often hear of and tends to make the outlook less dark.

In regard to the methods of operating, there are certain points that I want to speak of. I think that there is some danger in the advice just given to sponge the bladder freely, as in this way portions of the tumor may be, and I believe are, disseminated to other portions of the bladder. The method, proposed I think by Hagner, of lining the bladder with protective tissue during operation seems to me worth trying. Every

means should be taken to limit the bleeding as much as possible by the placing of preliminary sutures and rapid removal of the tumor when once the dissection is begun.

The question of drainage is an important one. It has been clearly shown that infection increases the rapidity of growth and probably favors recurrence. Drainage of the bladder tends to infection, particularly if that drainage be by the urethra. It is highly desirable to close these bladders as completely as possible, and if the bleeding has been thoroughly stopped it may be possible to dispense entirely with drainage. Schmidt, of Chicago, has laid particular stress on this point and advises the use of gas and oxygen anesthesia so that the recovery from the anesthetic may be rapid and the patients may regain control of their bladders early.

While the suprapubic route is at present the method of election for the majority of cases, I have no doubt that endovesical operating has a future. If the growths when first seen are of considerable size, open incision is probably the best method. Frequently when first seen the cases are well developed, but as the knowledge of cystoscopy increases, we shall get them earlier. Endovesical operating seems to me to be most favorable for the cases of multiple recurrences and single small recurrence. For these, repeated suprapubic operations are clearly undesirable. Some of the recurrences are frequently overlooked, and it is on the whole an unsatisfactory business. For these cases approach through the bladder seems to me highly desirable. At the present time we have the choice of two procedures, either the so-called operating cystoscope, of which there are several patterns, or the use of high-frequency current, as suggested by Keyes. If this latter method fulfills its promise, it will be of great value.

DR. A. L. CHUTE: It seems to me from my personal experience that Dr. Watson's advice is very important. In looking over my cases I find I have notes on 18 cases of malignant disease of the bladder. These were growths that infiltrated the bladder wall with one exception. This last was of the multiple papilloma type, but was found to be carcinoma on microscopical examination. Of these 18 cases, 15 have died; of the remaining 3, 1 was operated upon in July; another woman was operated upon a short time ago, but the mass was not removed; the other patient, the man with the multiple papillomatous growths that were reputed to be carcinoma, was operated upon two years ago. The growths were curetted through a suprapubic incision; he has shown no recurrence up to date.

In regard to Dr. Cabot's advice about protecting the bladder surface with gauze during operation, I believe that the method advised by some of the European surgeons, of swabbing it out with alcohol or iodine after operation, is more feasible.

One point not touched upon offers some hope to my mind, and that is that with further study we may come to recognize cystoscopically the precancerous stage of bladder growths. In many of the cases I have seen there has been a long history of bladder disturbance, showing that there must have been such a stage. In the case of one man who died of a massive infiltrating growth, the bladder trouble began with what was probably a typhoid cystitis that dated back to the time of the Civil War. A woman that I remember very well had a history of a stubborn cystitis that antedated the appearance of her carcinoma by many years. I believe it is perfectly possible that we may in time come to recognize cystoscopically the conditions that are forerunners of cancer of the bladder and by their removal forestall the malignant process itself.

DR. J. D. BARNEY: I should like to mention a case I saw at the clinic at the Massachusetts General Hospital. A man, thirty-five years old, who was operated on a year ago for two papillomata, one near each ureteral orifice. He came in the other day; had gained 60 lb.; had absolutely clear urine; no symptoms. Opposite the cystoscope as it went into the bladder there was a little tumor, perhaps the size of a bean, hanging down by a stem from the wall of the bladder posterior to the fundus. It is a case that would lend itself to the intravesical operation. It may be the result of dissemination at the time of operation and it also demonstrates the insidiousness of these papillomata, which may exist without any symptoms whatever.

DR. L. DAVIS: It seems to me that for a great many of these papillomatous growths the transperitoneal operation is not indicated. I cannot help thinking that it is considerably more dangerous than an ordinary suprapubic. I think it is a valuable operation where the tumor is inaccessible, or is sessile, or shows signs of infiltration. In the ordinary case I like to make the usual suprapubic incision; if the growth has a pedicle and is movable, it can readily be pulled up into view and excised with a good margin of mucous membrane. On the other hand, if you find the tumor is solidly attached, or has a broad, firm base, it is a simple matter to enlarge the wound into the peritoneal cavity and split the bladder in the median line. I have done that several times. I believe in suprapubic drainage of the bladder in all cases.

DR. P. THORNDIKE: Dr. Hagner, of Washington, is one of the younger operators who is insistent on the point of handling these tumor masses as little as possible. He takes every precaution against the dissemination of the disease as a result of the operator's technic. He has a scheme of operating with the aid of a cystoscope in the bladder, about which Dr. Cabot will tell us.

DR. H. CABOT: He makes the ordinary suprapubic incision down to the bladder, which is distended and exposed as fully as possible. Then, while looking through the cystoscope, needles or sutures are passed down through the bladder wall, thus outlining a good margin of healthy tissue about the growth. All the tissue between these points is then excised; in this way the handling of the tumor mass is avoided. Of course, this method is applicable to growths in the superior portion of the bladder only.

## WESTERN SURGICAL ASSOCIATION.

### TWENTIETH ANNUAL MEETING, HELD AT CHICAGO, ILL., DEC. 19 AND 20, 1910.

[Concluded from No. 6, p. 198.]

### INTUSSUSCEPTION WITH SPECIAL REFERENCE TO ADULTS.

DR. ELLSWORTH ELIOT, of New York City, stated that intussusception in adults was of more importance than previous study would indicate. The causes in children were largely confined to acute intestinal disturbances, while in adults they were more varied. The rarer causes were foreign bodies and parasites, less so ulceration from diarrheal diseases, tuberculosis, fecal masses, etc. A more common cause was trauma, especially severe muscular effort. Meckel's diverticulum was more common in children. The most frequent cause was a tumor, especially the benign polyp, with constricted base. The clinical course in children was fairly characteristic, while that in adults varied from one most acute to the very chronic. In his paper he tabulated three hundred cases arranged with reference to etiology and the clinical picture. Of the individual symptoms there was a great variety. Con-

stipation was the rule, but normal stool or diarrhea might occur. Blood or mucus in the stools was less frequent and usually signified a tumor. A tumor varying in size and shape, especially during the attacks of pain, and changing its position along the course of the colon, was characteristic. The tumor appeared first in the right lower quadrant, but should be looked for in the pelvis or in a position covered by the liver or spleen. Distention, general or focal, was variable. The course in the attack was usually very severe, especially in these cases with Meckel's diverticulum. In the protracted cases the natural processes might cause sloughing of the intussusceptum which was passed by rectum. Of these, forty-three cases were collected. Hope for such relief should not encourage conservative measures of treatment, for in usually less than eighteen months secondary obstruction occurred. He suggested, therefore, that after the acute symptoms had disappeared lateral anastomosis be done, connecting the bowel above with that below the affected portion. Treatment should in most cases be radical. With conservative measures complete reduction was never certain; recurrence was likely and the initial manipulation lowered the resistance to subsequent operation. Reduction in the first twenty-four hours was accomplished by combined expression and contraction in from ten to fifteen minutes, reduction by either alone being dangerous. Recurrence was avoided by anchorage of the cecum to the abdominal wall, by plication of the mesentery or by long longitudinal endoplication of the cecum along the anterior longitudinal muscular band. Gangrenous intussusceptum and intussuscipiens demanded resection followed by anastomosis or temporary enterostomy. A viable sheath might be split along longitudinally and through this the intussusceptum resected. Temporizing measures were entero-anastomosis and artificial anus. The procedure of choice was to gently reduce as far as possible and then resect. Complete reduction followed by resection was employed only where a tumor or the like was concerned.

He reported two cases; one in a male, aged forty. Following a history of severe cramps three months previously there was an acute attack lasting twenty-four hours with pain, vomiting, abdominal tumor, one normal stool, and blood in the rectum. Examination showed distended loops of the intestine. At operation there was an enteric invagination with a polyp the size of an English walnut near the apex. Recovery after resection. The second case was a female, aged sixty-seven, who had epigastric pain four months previous to operation; a clear interval until three weeks and then a recurrence sustained with a tumor in the region of the transverse colon. A high enema reduced the tumor, but obtained very little feces. There was no obstruction. Operation was delayed because of lack of symptoms and to increase her strength. Operation showed an ileocolic invagination with a polyp at the apex. Recovery took place after partial reduction, followed by resection.

### PRESIDENT'S ADDRESS.

Dr. John P. Lord, of Omaha, Neb., greatly deplored the giving of commissions and dividing fees, and said that realizing as he did that the practice of fee division, secret division, joint fees, commissions, graft and possibly money under false pretenses, was increasing at an alarming rate among the younger element, and that in many cities and towns it was the usual thing, he undertook to arouse the members from their seeming lethargy. Teachers and hospital surgeons, as a rule, were established in their respective communities, and had not felt the force of this evil to so great a degree as to compel action. Those who followed would feel it keenly. Many young men were wrestling with this moral problem and would yield to the general trend of practice unless some aroused moral force within the profession or the effect of publicity checkmated this menace to professional honor, dignity, common honesty and decency. He agreed with those who favored publicity as the speediest and most effective remedy. Then, too, they needed some Roosevelts to keep up a rapid fire attack upon this dishonest practice, and they should maintain a professional and public sentiment against any countenance of graft. The practitioners who had for years adhered to an inelastic fee bill found themselves with their financial wings clipped, and unable to rise above the level of customary fees. The specialist was something of a law unto himself and most often got what he asked. These practitioners, therefore, availed themselves of the specialist's faculty of fee getting and asking to add a sum for them, as the people would object to paying them a proper amount.

The medical schools had been remiss in their ethical instruction to students. The subject had been eschewed in some faculties for fear of engendering feeling, developing strife and endangering the integrity of the organization. The same silence had prevailed in medical societies because it might cost something to speak. Students were now without the close contact that was enjoyed in the days of the preceptors, whereas they now needed more of the moral and ethical side than ever before.

There had already been more harm done than could be overcome for a generation. Delayed action meant more sacrifice. The organized profession should busy itself in reformation and take its stand in the medical colleges, hospitals and societies, and as individuals and organizations educate the public and reform their own members. The most hopeful view might be taken of the result. Any practice which even smacked of graft or of obtaining money under false pretenses could not endure before a righteous public opinion. Nor would it continue in a profession which had cherished ideals from Hippocrates and the whole line of medical saints, religiously followed by the vast majority during all the ages of the history of medicine.

### INTESTINAL OBSTRUCTION DUE TO KINKS AND ADHESIONS OF THE TERMINAL ILEUM.

Dr. Charles H. Mayo, of Rochester, Minn., stated the stomach suffered from many reflex conditions; only one patient in ten with gastric symptoms showed actual lesions. Many bowel conditions, as obstruction, appendiceal concretions, simulated symptoms of ulcer. The development of the mid-intestine included from below the common duct to and including the part of the transverse colon. Ten inches of the ileum was pelvic, was originally fixed to the cecum, and becomes detached at first except for a lateral opening. When this failed to take place, obstruction was more liable to occur. In extensive appendiceal operations in cases with obscure symptoms, Mr. Lane had noted an intestinal kink near the ileocecal valve. He believed this to cause obstruction, often non-inflammatory, and probably resulting from traction of the loaded cecum to the pelvis. The symptoms often simulated those of appendicitis, ulcer and various forms of constipation. They had seen many cases of this nature, both of inflammatory and non-inflammatory origin, and producing reflex symptoms. Therefore, with the present increased facilities for intestinal exploration, the four terminal inches of the ileum should be examined when possible in obscure cases of digestive disturbance.

THE SELECTION OF OPERATION FOR INGUINAL HERNIA.

DR. ARCHIBALD MACLAREN and DR. HARRY P. RITCHIE, of St. Paul, Minn., gave the abridged records of 105 anesthesias showing 123 operations in 97 individuals. The greater number had come during the period of active life, and because of the occurrence of new symptoms or the failure of the truss to retain the hernia. No extraordinary measures, such as filigrees, flaps of the recti, were found necessary to obtain satisfactory repair. During the first decade, the operation without the most positive indications was often questioned. It was no odd experience to have the truss obliterate the sac, and when recurrence did come it would usually result in a less complicated form of hernia. During the second decade and beyond their advice was positive, as the presence of the hernia was then permanent. Two deaths had occurred, both from strangulated hernia. The total number of strangulations was 8; 3 of these were in the third decade and the remaining 5 in the sixth and seventh. Of the complications of convalescence, 7 cases had notes of wound infection, only 1 of which was severe. All cases suffering an inflammation to any degree were instructed particularly as to the possibility of recurrence. The appendix had been removed twenty-six times at the same time as the herniotomy, usually through a buttonhole in the internal oblique muscle. In one case a herniotomy and a cholecystectomy were done at the same time. Eighteen cases were operated upon for a double hernia. They had as easy a convalescence and there was no reason why the side opposite should not be investigated and a hernia in its inception cured. There was a record of 6 relapses, 2 of which were in women. The problem of the disposition of the wound ligaments was unimportant in relation to the cure of the hernia. Here the operation should be called a herniotomy and was not to be placed to the credit or discredit of any of the well-known methods. Of the 98 operations on men, there was one Halstead with cure, 55 Bassini's with one return, and 42 Fergusons with three returns. Previous to 1905 there were 2 cases in which from their description the cord was not displaced, but in all others (34 in number), a Bassini was done. One relapse had occurred and had been reoperated upon, but the remembrance of the technic of the first operation was such that the failure was ascribed to this rather than to the principle. Beginning in February, 1905, they were influenced in the use of the Ferguson operation. This was done as a routine operation forty-two times. The three returns had all been repaired, and the conditions found were identical in each case. There was no sign of the old hernia, but a new one had formed at the most dependent part of the canal. The sac came directly through to the inner side of the cord. When the sac was removed, it was easily demonstrated that if the tissues were replaced as before, that this defect would be uncorrected and there seemed to be no reason why the sac would not immediately recur. The only possible procedure was the use of the conjoined tendon and the displacement of the cord, thus performing a Bassini. The per cent of their success as to the displacement or non-displacement was in favor of the former. In view of the formation of an entirely new kind of hernia which came without displacement of the cord, and which they were powerless to prevent, it had swung the pendulum back in favor of the Bassini, and our present feeling was that if there was a recurrence, we would call it an operative fault and do it over again.

TYPHOIDAL CHOLECYSTITIS.

DR. JOHN E. SUMMERS, of Omaha, Neb., said that much discussion had taken place as to the mode of invasion of the gall bladder by the typhoid bacilli. According to Chiari, the route of infection was not by ascension from the intestinal tract, but his theory of gall-bladder infection by the typhoid bacillus was, first, the intestine, thence the blood and then the gall bladder.

Dr. Summers reported several cases, one of which was a pure case of typhoidal cholecystitis, the gall-bladder involvement giving symptoms at the beginning of the first relapse. The absence of any obtainable history of gallstones prior to the illness could fairly fix the initiation of the formation of the stone found in the common duct as taking place probably during the first part of the attack. The time from the beginning of the attack to the time of removal of the stone was from April 1 to Aug. 22 — sufficient time for its formation. In so far as he was informed, this was the first case of typhoidal cholecystitis with probable formation of the stone during the attack in which the stone was removed from the common duct. Cultures from the center of the stone were sterile, — a finding which did not negative the origin of the stone as due to typhoidal cholecystitis. Cholecystostomy upon typhoid carriers, he thought, should be done whenever there was evidence of any infection in the gall bladder or ducts. In cases where no signs of inflammation could be found, it might be considered that possibly the nesting-place for the bacilli was in the diverticulum and operation not indicated. There was favorable evidence for the carrying out of cholecystostomy in these dangerous persons.

PLICATION OF THE ANTERIOR BROAD LIGAMENT FOR RETRODISPLACEMENTS.

DR. A. W. ABBOTT, of Minneapolis, said the round ligament was not a natural support of the uterus, while the broad ligament was. Suture of the broad ligament just below the round ligament made an efficient support and conformed to the natural anatomical requirements. The operation was rapidly done. The failures were less than by other methods, and there was less pain after the operation.

ABDOMINAL EXCLUSION OF THE FUNDUS IN COMPLETE PROCIDENTIA.

DR. JOSEPH RILUS EASTMAN, of Indianapolis, Ind., stated that the question as to whether the uterus in its normal state was suspended by its liagments and thus secured in position or was supported or upheld by the muscles and fasciæ of the pelvic floor, the ligaments serving only as guides, became in the presence of complete procidentia a question of lessened importance, for in these extreme cases hysterectomy or the abdominal operation with fixation was absolutely necessary, in addition to a thorough repair of the vaginal supports, with amputation of the elongated portio vaginalis and curettage. The fixation here referred to was not a classical one by which the fundus was sutured to the abdominal aponeurosis, but one in which the uterine fundus was drawn quite through the abdominal wound, the entire fundus being excluded and secured with a large transfixing pin. The pin was allowed to remain in place for two and one-half weeks. It was not a rare experience to find a few months after a simple fixation the abdominal wall sunken in at the site of fixation and the prolapsus returning. In exeluding the fundus in cases of complete procidentia, the aim had been to fix the uterus higher than could be done by an ordinary fixation, to provide for firm attachment of the peritoneum, muscles and aponeurosis at a low level upon the anterior, posterior and lateral aspects of the uterine body. All of the layers of the abdominal coverings were drawn snugly around the uterine body and

sutured to that organ anteriorly, posteriorly and laterally. The transfixing pin in the three cases reported was passed deeply enough to exclude the entire fundus. Two patients thus operated, though they were past fifty years of age, had not passed the menopause, and in one of these the uterine appendages were removed and in the other the tubes were divided and the peritoneal screen suggested by Ries interposed. In all three cases the abdominal operation was preceded by curettage, amputation of the cervix, anterior and posterior colporrhaphy and perineorrhaphy. In each case the fundus had been covered over with skin growing centrally from the periphery within two or three weeks. Owing to the firmness of the attachment and the elevation given by the transfixing pin, the possibility of sagging or detachment was minimized. The method offered the greatest possible uterine surface for fixation in the abdominal coverings. It made possible reduction of deformities caused by extreme relaxation as a simple intra-abdominal fixation could not do because the uterus was drawn higher and the firmer fixation prevented a yielding ligamentous fixation or a complete sundering of the attached structures, an accident which was perhaps less rare than was imagined.

LESIONS OF THE HIP-JOINT AND THEIR MANAGEMENT.

Dr. John B. Murphy, of Chicago, spoke of the elements in connection with lesions of the hip-joint and of an important principle governing the final results obtained in pathological conditions and in fractures. In his recent work in connection with fractures, in attaching the upper end of the femur frequently he found a definite condition occurring, namely, absorption of the neck. No such absorption took place in fractures in any other part of the body. It never occurred when there was a fracture in the upper end of the humerus. This absorption was due, he believed, to the primary condition of the circulation in the neck of the femur. When there was a fracture, a lesion or disease, the repair of that lesion depended more upon the condition of the circulation in the neighborhood than on any other one thing, taking into account always the regenerative potency of the individual structure. In fractures that occurred close to the head of the femur there was practically no absorption at all; no fatty degeneration, no breaking down, no liquefaction of bone. When a fracture occurred close to the base of the neck and there was attachment to the trochanter, it did not tear off the blood vessels in the capsule inside. That capsule went down and out and back in again, and the blood vessels went in a proximal and distal direction, but the bone for a certain distance in a great majority of cases was absorbed. If there was a fracture of the neck of the femur which did not tear off the blood vessels, then the portion between the trochanter and the head remained, and it was capable not only of revascularization, but of ossification, regeneration and of sustaining the neck.

In the management of fractures of the femur, it had been the custom to dress them with a straight external splint. What did this do? It tended to shortening by shortening of the adductors, and shortening of the gluteal group of muscles attached to the trochanter, and not only that, the tendency of the adductors was to draw the limb inward, and there was shortening in that position. What the surgeon wished to do was to reduce to a minimum contraction during the process of absorption of this portion of the head of the femur, so that when absorption had taken place and the tissues were ready for regeneration, it was essential to have the parts in apposition. They could be best maintained in apposition by relaxing the group of muscles which did so much to cause shortening by putting on extension. The ambulatory management of tuberculosis of the head of the femur was wrong in his opinion. An ambulatory apparatus was applied to prevent motion, and as far as it inhibited motion in a joint it was valuable. But what should it be applied for? To prevent pressure on the inflamed part. When the products of infection were held under tension there was rapid destruction of tissue. This tension should be relieved. The first main principle should be to separate these articular surfaces by an extension apparatus, and then build up the patient to stimulate the process of repair.

Dr. B. B. Davis, of Omaha, Neb., read a paper in which he spoke of Meckel's diverticulum as a cause of ileus.

OFFICERS.

President, Dr. Amos W. Abbott, Minneapolis, Minn.; First Vice-President, Dr. A. E. Halstead, Chicago, Ill.; Second Vice-President, Dr. William Frick, of Kansas City, Mo.; Secretary-Treasurer, Dr. Arthur T. Mann, Minneapolis, Minn.

Kansas City, Mo., was selected as the place for holding the next annual meeting, and time, Dec. 18 and 19, 1911.

## Book Reviews.

*The Working People.* Their Health and How to Protect it. By M. G. Overlock, M.D. Worcester, Mass: The Blanchard Press. 1910.

This well-meant volume, whose author's titles are arranged in a novel Pindaric variation of the fashionable inverted truncated pyramid, contains an interesting assortment of sound advise, sagacious truisms, and some harmless fallacies. Its style is dogmatic but probably well adapted to the "plain people" to whom it is addressed. On the whole, the effect of the book is good and it will doubtless do good if read by those for whom it is intended.

*Otitic Cerebellar Abscess.* By Heinrich Neumann. Translated by Richard Lake, F.R.C.S. 8vo. Pp. 156. London: H. K. Lewis. 1909.

This little volume is a careful study of otitic cerebellar abscess, based partly on former statistics collected by the author and partly on a new collection of 156 cases. Middle-ear suppuration, associated with cholesteatoma, is the chief etiological factor. The clinical picture often shows few definite characteristics, and many cases run a latent course. The chief focal symptoms are those due to lesion of Deiter's nucleus, — vestibular nystagmus, vertigo and vestibular ataxia; or of the sensory tracts — hemiparesis and hemi-ataxia. The researches of Bárány receive full consideration. About one fourth of the cases are cured by operation. Operation from the middle ear is preferred to opening the abscess through the skull, as extirpating the primary focus of suppuration. The work is a valuable and important study of cerebellar abscess. The style of the translation is somewhat involved, and the book lacks any index, but it will prove of much assistance both to the aurist and the neurologist.

THE BOSTON

# Medical and Surgical Journal.

THURSDAY, FEBRUARY 16, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: $5.00 *per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 503 Paddock Building, 101 Tremont Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.*

*Remittances should be made by money order, draft or registered letter payable to*

W. M. LEONARD,
101 TREMONT STREET, BOSTON, MASS.

## FACTORY AND SCHOOL HYGIENE.

THE third annual report of the Massachusetts State Board of Health upon the work of the state inspectors of health shows by its clear presentation of facts relating to the hygiene of factories and schoolhouses that the inspectors have accomplished a vast amount of good both in a practical and educational way.

A notable feature of the report is the description of the actual results obtained from the inspection of factories. In all establishments where workers were found unprotected against irritating dusts arising from metal or emery polishing, adequate protective provisions were insisted upon. Dirty windows and dirty interiors were cleaned, with such marked improvement in the light that workmen employed at processes requiring attention to detail appreciated the changes and performed their work better and more easily. Ventilating provisions were altered even to the extent of installing a new artificial ventilating system in order to obtain adequate ventilation of workrooms. Drinking water supplies were made safe, and tanks from which the water was furnished cleaned and so altered as to be accessible for cleaning. Radical improvements were made in toilet room conditions, resulting in the expenditure by manufacturers of many thousands of dollars, and in some instances in the employment of a man for the sole purpose of keeping the closets in a sanitary condition.

Of equal importance is the educational work done both among employers and employees. It appears that the workers frequently fail to appreciate the dangers to which they are exposed, hence are indifferent and oftentimes even opposed to the use of protective appliances.

Another important feature of the report is the literature contributed to the subject of occupational hygiene; for example, the hygiene of candy and chocolate factories, of cigar factories, of metal working establishments and of jewelry making and its allied industries.

During the period covered by the report some 2,800 industrial establishments were thoroughly inspected, and about 500 reinspected. Of some 600 objectionable conditions called to the attention of manufacturers, more than 400 were satisfactorily remedied. Of nearly 14,000 minors seen and questioned, 945 were examined physically and 181 found with some abnormal condition. While inquiring concerning the health of the minors in one factory the state inspector of health discovered signs of beginning tuberculosis in 11 minors. The inspector reported the cases to both state and local health authorities and assisted the local board in placing the minors under treatment, thereby insuring proper care and protection to the public.

Such work as the health inspectors are accomplishing in our industrial establishments emphasises the need of furthering the study of factory and occupational hygiene throughout the country on such a scientific basis as that now well established by the Massachusetts State Board of Health, and of including in the investigation of the prevalence of communicable diseases and dangerous influences within the factory, inquiries concerning the health of adults as well as minors. In this work the position of the health inspectors is unique, for they are constantly in touch with the prevalence of diseases in their respective districts and, further, with practicing physicians whose assistance they frequently get not only concerning communicable but occupational diseases. It has thus remained for the state of Massachusetts, the state which established the first State Board of Health in this country, to lead all other states in the recognition of the fact that the inspection of industrial establishments by well-trained medical men under the supervision of a board whose duty it is to study the health of the community in its broadest sense — the State Board of Health — means the promotion of public health. The factory cannot be divorced from the community, especially in the large industrial centers where the community is composed largely of factory workers. As the report makes evident, it is of the greatest importance in order to guard the public health that the physicians who are familiar with the hygiene of towns and cities and are constantly investigating tuberculosis and other communi-

cable diseases shall remedy the unsanitary conditions in our factories and do all within their power to prevent the spread of diseases in these establishments and, by virtue of their knowledge of outside unhygienic influences, study thoroughly the possible effects of industry upon health.

The investigation of schoolhouse conditions made with the view of better protecting the health of the pupils discloses an equal need of authority to improve the hygiene of these buildings. Some 250 schoolhouses were carefully examined and reported upon, but the State Board of Health, owing to statute limitations, can only investigate and report to the Legislature the results of their findings, so that the efforts of the board to guard against ill-ventilated or overcrowded schoolrooms depend at present upon the willingness of the community to accept the facts disclosed and to act upon them. While in a number of instances new schoolhouses have been constructed as the result of the examinations made by the health inspectors, the State Board of Health are not authorised to require changes in the sanitation of old buildings.

## PROPOSED HOMŒOPATHIC SANATORIA FOR CONSUMPTIVES.

There was introduced last month before the State Legislature a resolve accompanying a petition of the Massachusetts Homœopathic Medical Society for legislation to provide for the establishment of a homeopathic sanatorium for tubercular patients. The provisions of this proposed measure are: First, that an appropriation of $100,000 be made "for creating a new sanatorium for tubercular patients to be situated in the eastern part of Massachusetts, that shall provide homeopathic medical treatment for all patients who desire it by such number of homeopathic physicians as may be necessary, and which shall be under the direction, management and administration of homeopaths"; second, that the already existing sanatorium at North Reading be also "placed under the direction, management and administration of homeopaths"; third, that the number of trustees on the board of trustees of the Massachusetts hospitals for consumptives be increased from seven to ten, "of which number there shall be at least three homeopathic physicians, members of the Massachusetts Homœopathic Medical Society." The need or desirability of such important changes deserves careful investigation.

At present the situation as regards representation of homeopaths in the state hospitals for tuberculosis is as follows: In the sanatorium at Rutland, which has 350 beds, there are two services of equal size, to which patients are assigned alternately, and of which one is administered by homeopaths, the other by regular physicians. No patient at this institution has ever made a request for homeopathic treatment, and as a matter of fact the treatment given on the two services is absolutely identical. In the three other state sanatoria, at Lakeville, Westfield and North Reading, which have 150 beds each, all the medical assistants have hitherto been regular physicians, but from no patient at these institutions has request ever been made for homeopathic treatment. Last fall representation at these hospitals was requested by the homeopaths, and the board of trustees then agreed to appoint homeopathic medical assistants at all of them, and requested nominations and applications for such appointment. Since that time no nomination and only one such application has been made, the latter from a man obviously unfit to serve in any medical capacity.

In view of these facts, it does not seem that the present situation is one of injustice to homeopaths, either physicians or patients, since they have, or are to have, under the existing arrangement, representation at the several institutions. Under the proposed measure, they ask to have two sanatoria placed under their entire control, representing, with their share of beds at Rutland, one half the public provision for consumptives in the state. But there is no evidence that this request represents a desire of the community. Not only has there been no request for homeopathic treatment from any patient at these institutions, but of 298 physicians making request for admission of patients to them last year, only 27 were homeopaths. Moreover, there is in the state only one private provision for the homeopathic treatment of consumptives, — in some cottages maintained at Rutland. Were there a genuine popular demand for such treatment, there would be other such private institutions, there would be requests for homeopathic treatment at the state sanatoria, there would be applications for homeopathic medical appointments at these sanatoria.

The query, furthermore, may pertinently be made, "What is the homeopathic treatment of tuberculosis, and wherein does it differ from that given by regular physicians?" We have seen that the methods of treatment are identical on the two services at Rutland. Consumption is a

disease treated not by drugs, but by diet and hygiene, and the truth of hygiene is everywhere the same. Is it proposed to administer food and fresh air in homeopathic doses? If there were any reason for the establishment of an exclusively homeopathic hospital for tuberculosis, there would be the same reason for establishing similar institutions for representatives of any other exclusive dogma.

We do not believe that the present situation is unfair to the homeopaths, or that their request for legislation represents a popular demand or is based on a genuine necessity, and we fail to see on what grounds the proposed bill is to be recommended.

## INTERNATIONAL CONGRESS ON HYGIENE AND DEMOGRAPHY.

PRELIMINARY announcement is at hand of the Fifteenth International Congress on Hygiene and Demography, which it is proposed to hold in 1912 at Washington, D. C. The Fourteenth Congress, in 1907, met at Berlin, and the coming session would be the first to be held outside of Europe. The responsibility for its conduct has been assumed by the United States Department of State, and official invitation to send delegates has been accepted by twenty foreign governments. Dr. Henry P. Walcott, of Cambridge, Mass., is to be president of the congress, and Dr. William H. Welch, of Baltimore, Md., chairman of the executive committee. There will be nine sections devoted to the following subjects: Hygienic microbiology and parasitology; dietetic hygiene and hygienic physiology; hygiene of infancy and childhood and school hygiene; industrial and occupational hygiene; control of infectious diseases; state and municipal hygiene; hygiene of traffic and transportation; tropical, military and naval hygiene; demography.

The special purposes of this congress, as stated in the preliminary announcement, are: First, to know and to make known our sanitary achievements in the Canal Zone, in Cuba, in Porto Rico, in the Philippines and in Hawaii; second, to strengthen and harmonize the efforts of federal, state and municipal governments in relation to public health and vital statistics; third, to correlate and economize the activities of many unofficial organizations dealing with questions of public health.

The estimated total cost of the congress is $100,000, of which probably $60,000 will be furnished by the United States government. To secure assurance of the remaining $40,000, the committee on organization is making this early announcement with the request for subscriptions for advance membership from physicians and others interested in the purposes of the congress. This request should meet with a generous response in order to insure the success of an undertaking which not only should be a credit to this country, but should also result in valuable contributions to the science of hygiene and its practical application.

## PREPARATION OF ANTI-MENINGITIS SERUM.

IN accordance with an announcement made last summer, the Rockefeller Institute for Medical Research gives notice this week that it has discontinued the general distribution of anti-meningitis serum and will devote to other lines of investigation the funds hitherto employed for this purpose. The serum, whose effectiveness in that form of meningitis due to the diplococcus intracellularis of Weichselbaum may now be regarded as established, must henceforth be prepared, like vaccine and diphtheria antitoxin, by public health authorities and commercial establishments. At present the Board of Health of the City of New York has undertaken its regular production and local distribution. Similar provision will probably be made by boards of health in other localities.

This action of the Rockefeller Institute marks the closing step in a very brilliant piece of scientific research which has contributed to practical medicine another valuable agent in the conflict against disease. Statistics indicate that early use of the serum in bacteriologically authenticated cases has reduced the mortality of this form of meningitis at least 65%.

## LARGE AND SMALL FAMILIES.

AT the joint meeting of the Twentieth Century Club and the Boston Milk and Baby Hygiene Association, to which reference is made in another column, there seems to have been some difference of opinion between President Eliot and Dr. J. L. Morse relative to the desirability of encouraging large families among the poor. Dr. Eliot holds that early matrimony and the begetting of many children is nature's law, the violation of which has produced many of the evils of society. Dr. Morse, on the contrary, cites the proposition, recognised by the thrifty but not by the improvident, that no family should produce

more offspring than it can properly care for. This principle applied would make the size of families proportionate to wealth. Mr. Eliot's doctrine is doubtless a wholesome reaction from the pernicious dogma of the Neo-Malthusians. The trouble is that each appeals to the wrong class of persons. What is really needed in society is not more children, but more children of the right sort. Unfortunately it is often as difficult to make the fit procreate as it is to prevent the unfit from doing so. Probably in spite of all reformers, nature will continue to solve the problem after the method of the centuries.

## MEDICAL NOTES.

Poliomyelitis in Oregon. — It is stated that during the past year acute poliomyelitis has been extensively prevalent in Oregon. During the fall of 1910, 94 cases and 12 deaths of the disease were reported to the State Board of Health, but these figures probably represent only a portion of the actual morbidity and mortality.

Chimerical Expectations from Radium. — The daily press has lately contained items relative to the marvelous rejuvenating effects of intravenous injections of radium, and to the possibility of its affording an inexhaustible supply of heat and energy to the world. However future chemical discoveries in regard to radium and allied elements may lead to upsetting or revision of the atomic theory, it is needless to say that such expectations are as chimerical as the philosopher's stone or the *elixir vitae*.

An Undaunted Centenarian. — Foster J. Foster, of Kansas City, grandson of a former chief of the Seneca Indians, is alleged to have been born in 1804 on the site of Buffalo, N. Y., then an Indian village. For many years he served as a government scout and secret service agent. At present he is reported as engaged in litigation over a mining claim in Montana, and is said to have announced that, in the event of his failing to recover the property, he intends to go into business and make an entirely fresh start in life. Such unabated zeal and perseverance would be creditable in a person of half his reputed age.

A Precocious Great-Grandmother. — In the issue of the Journal for Jan. 26, we noted that Victor Beyson, of Spencer, N. C., had just become a grandfather at the precocious age of thirty-three. Report from Baltimore now states that Mrs. Addie Ward, of Mecklenburg County, North Carolina, became a great-grandmother in April, 1910, at the age of forty-five. Mrs. Ward was born in December, 1864. Her oldest daughter, now Mrs. A. J. Lawing, was born in 1878. Mrs. Lawing's oldest daughter, now Mrs. W. A. Adams, was born in 1895. And Mrs. Adams's first child, also a daughter, was born in 1910. Precocious matrimony seems to be hereditary in the female line of this family.

Psychic Healing and Tuberculosis. — Dr. J. L. Pomeroy, in a paper on "Psychic Healing and Tuberculosis" in the *Journal of the Outdoor Life*, says: "One of the saddest things that has come to my notice is that of a girl cured of tuberculosis trying to convince her Christian Science mother that her brother is in the first stages of tuberculosis. No matter how much internal rest is produced by a method, it must not injure our reasoning power in regard to our fellow beings. In this we physicians should have a word to say."

### BOSTON AND NEW ENGLAND.

Acute Infectious Diseases in Boston. — For the week ending at noon, Feb. 7, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 49, scarlatina 42, typhoid fever 5, measles 110, smallpox 0, tuberculosis 75.

The death-rate of the reported deaths for the week ending Feb. 7, 1911, was 17.71.

Boston Mortality Statistics. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Feb. 11, 1911, was 260, against 244 the corresponding week of last year, showing an increase of 16 deaths, and making the death-rate for the week, 19.68. Of this number 139 were males and 121 were females; 251 were white and 9 colored; 153 were born in the United States, 102 in foreign countries and 5 unknown; 60 were of American parentage, 174 of foreign parentage and 26 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 45 cases and 2 deaths; scarlatina, 49 cases and 2 deaths; typhoid fever, 6 cases and 1 death; measles, 72 cases and 0 deaths; tuberculosis, 91 cases and 24 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 57, whooping cough 3, heart disease 29, bronchitis 5. There were 16 deaths from violent causes. The number of children who died under one year was 42; the number under five years, 60. The number of persons who died over sixty years of age was 72. The deaths in public institutions were 102.

SEIZURE OF FROZEN EGGS. — Another seizure of frozen eggs was made in Boston last week by the United States deputy marshal. The shipment, which consisted of 10½ cases containing a total of 3,400 dozen eggs shelled and canned, was made from a Chicago firm to its local office.

DENTAL INSPECTION OF SCHOOL CHILDREN AT DEDHAM. — It is reported that the school committee of Dedham, Mass., has accepted the recent offer of a number of local dentists to give each a half-day every month to free dental inspection of the public school children of the town.

DIRECTOR OF MAINE GENERAL HOSPITAL. — Report from Augusta, Me., announces the nomination, on Feb. 7, of James C. Hamlen as director of the Maine General Hospital at Portland, to succeed Franklin A. Wilson, of Bangor, who recently resigned.

NEW DIRECTOR OF HOLY GHOST HOSPITAL. — At a meeting of the directors of the Holy Ghost Hospital for Incurables, held in Boston last week, Mrs. Curtis Guild, Jr., was elected a member of the board to fill the vacancy caused by the death of Mr. Carstein, of Cambridge.

TWO BEQUESTS TO HOSPITALS. — The will of the late Anna C. George, of Haverhill, Mass., filed last week for probate, contains a bequest of $1,000 to the Hale Hospital, at Haverhill.

In the will of the late Caleb S. Hollis, of Braintree, Mass., allowed in probate last week at the Norfolk Probate Court, the Quincy (Mass.) City Hospital is named as residuary legatee, and will probably receive a considerable sum from the estate.

INFANT MORTALITY IN MILL TOWNS. — At a joint meeting of the Twentieth Century Club and the Boston Milk and Baby Hygiene Association, held on Feb. 10, to discuss the prevention of infant mortality, addresses were made by President Eliot, by Dr. John L. Morse and by Mr. Walter Kruesi. The latter commented especially on the exceptionally high infantile death-rate in manufacturing and mill towns, such as Fall River, Lowell and Salem.

REPORT OF ST. MONICA'S HOME. — The recently published annual report of St. Monica's Home, Roxbury, for the year ended Oct. 30, 1910, shows that during the year forty-three new patients were admitted to the institution. About one third of these were cases of pulmonary tuberculosis. The need of increased accommodation for patients with other chronic diseases could advantageously be met by the purchase and equipment of an adjacent brick building, for which the sum of $3,500 is required. It is earnestly hoped that this amount may be raised by charitable subscription during the coming year.

WORK OF ELLIOT HOSPITAL, MANCHESTER, N. H. — The annual report of the trustees of the Elliot Hospital of Manchester, N. H., shows continual progress in the work of that institution. During the year 1910, 327 patients were treated, a considerably larger number than in any previous year. During that year 29 physicians personally sent patients to the hospital, which demonstrates the wide field of usefulness it is covering. Like most progressive institutions, the hospital is in need of financial aid, since from its opening in 1890 the trustees have been obliged to contend with an annual deficit.

### NEW YORK.

CONVICTIONS FOR SALE OF WOOD ALCOHOL. — On Feb 6, the first convictions in the Federal Courts under the new law forbidding the sale of wood alcohol as a beverage were secured. The accused are three officials of the Empire Rectifying Company of Brooklyn, and by Judge Chatfield, in the United States District Court, they were each fined $250 and sentenced to prison. The terms of imprisonment were respectively, nine, four and three months.

REPORT OF STATE COMMISSIONER IN LUNACY. — The annual report of the State Commission in Lunacy, transmitted to the Legislature on Jan. 31, states that the total number of insane in the state on Sept. 30, 1910, was 32,658. The number in the state hospitals for the insane was 31,606; in the Matteawan and Dannemora hospitals for insane criminals, 1,161; and in licensed private institutions, 1,052. The total number of patients received during the year was 7,063, the net increase for the year in all institutions being 1,119. The report announces that at an early date addresses on the prevention of insanity will be made at the Academy of Medicine, New York, and later in many parts of the state, to be followed by a series of public lectures illustrated with moving pictures depicting the life of the insane and the remedial measures employed in the modern hospitals. Pamphlets will also be issued, informing the public of the avoidable causes of insanity, for distribution to high schools, colleges, church organizations and philanthropic societies.

REPORT OF COMMISSIONER OF HEALTH. — The annual report of the State Commissioner of Health was submitted to the governor on Feb. 6.

Last year 212,795 births were reported, or 10,139 more than in 1909. The city having the highest birth-rate, 32.7, was Dunkirk, and that having the lowest, 11.9, Troy; a condition, it is stated, due in part to incomplete registration. In the latter city 681 more deaths than births were reported. In New York the birth-rate was 27.1. The total number of deaths in the state was 147, and the death-rate was 16.1, the urban and rural rates being the same. The lowest death-rate, 11.8, was in the city of New Rochelle, Westchester County. The reported mortality from tuberculosis was 14,047, or 9.5% of all deaths. Some reduction in the mortality from this disease, however, is noted. For a period of twenty-five years the percentage was 11. In 1909 it was 10, and in 1910, as stated, 9.5. An increase in the deaths from cancer is noted, and the establishment of the proposed hospital in connection with the State Cancer Laboratory at Buffalo is strongly recommended. An increase in the appropriation for the investigation and control of communicable diseases is also urged. "From an economic standpoint alone," the report goes on to say, "it is entirely possible to save thousands of lives and millions of dollars to the state. Our greatest natural resource is the child. In the prevention of infant mortality alone the state could well afford to spend all that it now appropriates for the Department of Health." The report furthermore points out that much of the public health law was enacted thirty years ago, and is, therefore, inadequate for the demands of the present day; and while a large increase in the powers of the department is not advocated, it is argued that sufficient authority should be vested in it to enable it to improve many unsatisfactory conditions. At present the department is empowered to make sanitary investigations, but to a large extent lacks the authority needed to enforce the changes called for.

Reports of Health Department. — The weekly reports of the Health Department show that the mortality in the city during the month of January represented an annual death-rate of 16.54, as against 17.18 in December and 17.54 in January, 1910. The decline in the mortality is doubtless due to the milder weather which prevailed in January, though in the early part of the month there was a sudden and marked increase in the deaths from influenza. Thus, while the number of deaths reported from this cause in the last week of December was 27, in the first week of January the number ran up to 51. By the last week of the month, however, it had declined to 24. Pneumonia was also unusually fatal in the first week of the month, causing 216 deaths, but by the last week the number of deaths was reduced to 114. Among the diseases in which there was a diminished mortality were the following: The weekly average of deaths from typhoid fever decreased from 11.75 in December to 5.5 in January; the weekly average from acute bronchitis, from 25 to 22.25; from pneumonia, from 191.25 to 172.75; from bronchopneumonia, from 119.75 to 107.5; from diarrheal diseases, from 43.5 to 39; from organic heart diseases, from 188.5 to 184.5; from appendicitis and perityphlitis, from 12.75 to 11; and from Bright's disease and acute nephritis, from 125.75 to 123.25. Among the diseases in which there was an augmented fatality were the following: The weekly average of deaths from measles increased from 5 to 7.5; from scarlet fever, from 10 to 14; from whooping cough, from 5.5 to 6.75; from diphtheria and croup, from 25.25 to 29.75; from influenza, from 18.75 to 35.25; from pulmonary tuberculosis, from 170 to 186.5; from cancer, from 69.25 to 71; from apoplexy and softening of the brain, from 25.75 to 36; and from puerperal diseases, including septicemia, from 12.5 to 15.75. The corrected death-rate, excluding non-residents and infants under one week old, was 15.73.

Popular Lectures on Modern Medicine. — In opening his course of popular lectures on modern medicine at the American Museum of Natural History, Prof. Frederic S. Lee said: "In accepting the Jessup lectureship I was influenced largely by the thought that through it I might perhaps be of service to both the medical profession and an intelligent public by telling the public something of what medical leaders are doing. Notwithstanding the swift progress of medical science, we frequently meet with a distrust of the efficacy of medicine, a feeling that the physician knows far too little concerning disease and its cure, and a tendency to turn towards strange cults, making fair promises. Such distrust is as old as medicine itself. I do not believe that it is justified." The subject of this first lecture was the normal human body, ignorance in regard to which he declared to be extraordinarily great. "It is strange," he said, "to find thinking, reasoning men and women, who were born with their bodies, who have clung to them in sickness and in health, who have used them for every variety of human service and yet

hold themselves aloof from a knowledge of bodily affairs. I suspect that we have here an inheritance, through many generations, of the medieval notion of the vileness of the human body, a notion which is out of keeping with the enlightened science of to-day. This science shows within ourselves wondrous mechanisms and adaptations which ought to arouse any man's admiration. At one point he illustrated the complexity of the human organism by describing the various forces brought into play in the simple act of lifting one's arm, and went on to say: "We may, in our bewilderment, well wonder why a mere innocent contraction of the biceps does not bring in its train an attack of nervous prostration. Seriously, this great complexity is not appreciated. Gay critics, the anti-this and the anti-that, grow impatient with medical science and turn to others who profess to work successfully with simpler methods. But those to whom they turn are utterly unfamiliar with the complexities of the human body and its functions, complexities that are far beyond the anti-this and the anti-that."

1. Richardson, in his paper on cancer of the breast, emphasizes many practical points that can come only to one who has had a large experience with this disease over many years. The following are some of the most important: The only treatment of breast tumors which as yet gives any real hope of permanent cure is thorough removal by operation. Operable cancer should never be subjected to any other method, for precious time is sure to be lost. The preliminary trial of the x-ray is one of the glaring instances in which patients go from operability to hopelessness. Early diagnosis does more to give good prognosis than anything else. The only factor for success is the early, invariable thorough extirpation of all breast tumors in which there is any doubt as to their nature. All non-operative methods must be strictly confined to the inoperable cases. Richardson is inclined to advise operations on all breast tumors, whether the diagnosis points toward malignancy or not, provided the patient is of the cancer age. A diagnosis of benignancy is positive enough to contraindicate operation if the patient is not of the cancer age and if the history and signs favor benignancy, but if the patient is of the cancer age a reasonably certain diagnosis of benignancy is not strong enough to justify the postponement of operation unless there are contra-indications to operation other than the tumor itself. The slightest suspicion of malignancy should demand operation, especially at the cancer age. In all tumors of the breast the presumption should be that they are malignant until they are proved benign.

4. Douglas finds that many infants are fed a too high percentage of fat. They are either born with an imperfect fat digesting power or very rapidly acquire it through the overfeeding of it. The overfeeding of either fat, protein or sugar will very soon materially limit or entirely destroy the power to digest that food. There is always less difficulty in feeding fat to normal infants during the first months than to those who are older. It is a serious mistake to increase the proportion of fat for its laxative effect. If a small increase of 1% does not promptly produce the desired softening effect, no further increase will do it, but will do harm. He advocates the use of rice, which contains a low fat per cent and a negligible content of crude fiber and is, on the whole, much more digestible and suitable in these cases than either barley or oatmeal.

14. Schamberg and Ginsburg advise against the use of salvarsan in myocarditis, in advanced cases of tabes dorsalis and general paresis, in nerve syphilis affecting vital centers, in grave kidney disease, in cachetic and debilitated persons, in aneurysm, in optic neuritis and in persons with lesions (such as gastric ulcer) in whom increased blood pressure may produce hemorrhage. It is unsafe under any circumstances to inject into the veins a solution which is not perfectly clear, or to inject the salvarsan into the veins without previously running in physiologic salt solution, or to infuse a cold solution. A routine dosage should never be used; the dose should be gauged according to the weight of the patient and the character of the

condition to be treated. Intravenous injections should not be given in the office or in a dispensary. The patient should always be treated where he can be put to bed and carefully observed for a period of not less than three days. [E. H. R.]

1. Stengel's article deals with the condition characterized by repeated sudden attacks of dyspnea with frothy, often blood-stained sputum, occurring usually in connection with cardiac insufficiency, especially in the presence of high arterial pressure. A critical review of experimental evidence makes it probable that an important factor in production of the disorder is a disproportionate action of the right and the left ventricle, with abnormal congestion in the pulmonary circulation, with perhaps as a subsidiary cause an abnormal permeability of the pulmonary vessels. In treatment chief reliance is to be placed upon morphia, which empirically acts as a specific in relieving the attack. Nitroglycerine may be of service in mild attacks, but fails entirely in those more severe. Venesection is efficacious but unnecessary. Between attacks avoidance of overexertion and excitement, restricted diet, treatment of renal disorder if present and cardiac stimulation by caffein or digitalis may be desirable.

2. Elsner emphasizes the importance of diseases based upon arteriosclerosis and expresses the belief that their frequence is increasing. He, therefore, outlines a system of treatment by which he believes that the occurrence of arteriosclerosis is to be diminished. He believes that arteriosclerosis and its distribution can be traced largely to the overtaxing of the various organs involved and urges avoidance of all overtaxing of the various functions. Tobacco and coffee are to be used in great moderation, also alcohol. Excesses in diet are to be corrected. Excessive mental activity is to be avoided, also excessive coitus. Muscular exercise in advanced cases is to be regulated by passive motions of the Zander type, and by hydrotherapy. High-frequency currents are recommended. Of drugs, the iodides, theobromine and digitalis may be useful according to circumstances. In cases with sensory symptoms the nitrites are of service.

3. Schmoll calls attention to the recent recommendation of the continuous use of digitalis in small doses in heart disease for a tonic effect, to prolong the efficiency of the myocardium, particularly in cases of valvular disease of rheumatic origin. He believes it indicated from the first appearance of signs of loss of tonicity, râles at the bases of the lungs, enlargement of the liver or slight edema of the ankles, in doses amounting to 0.1 gr. a day.

4. Meara contributes a valuable didactic discourse on the treatment of typhoid fever, but with little that is not generally known. In diet he urges the acceptance of the more liberal ideas of feeding that have in recent years superseded the undernourishment in the past, giving as illustrations the diets now in use in several modern hospitals. He is emphatic as to the advantages of hydrotherapy, but warns against its too heroic application. In prophylaxis, attention is directed to the benefits of preventive inoculation.

5. Doty presents evidence that in certain cases of cholera the incubation period may be prolonged or a period of weeks, and that there may be "carriers" in whom the symptoms of disease never appear. These cases cannot be detected in quarantine stations; each community should provide for prompt detection of the disease and isolation of cases. With modern sanitary regulations, however, there is little danger of widespread epidemics.

6. Lichty has studied 249 cases of disease of the gall bladder with reference to gastric symptoms. In 156 of these, gastric analyses were made. In 54% he found hyperacidity, and in many a diminution of gastric motility. He believes that hyperacidity should be regarded as evidence of some definite lesion in the gastro-intestinal tract or its appendages.

7. Niles describes the dyspepsias peculiar to old age as depending largely upon a disproportion between appetite and digestive power, either from inability to ingest sufficient food from a too early sense of repletion, or from loss of the normal sense of repletion with consequent overeating.

8. Stoll maintains that insufficient attention is paid to the diagnosis of bronchial gland tuberculosis and summarizes the various diagnostic signs which may be of value, as illustrated by a series of cases. Of symptoms he mentions the insidious onset of languor, cachexia and irregular pyrexia, later cough of "brassy" quality, sometimes respiratory stridor, sometimes hemoptysis. Of the numerous physical signs to be looked for he mentions dilated thoracic veins, tenderness over the manubrium sterni, tenderness of upper thoracic vertebral spines, mediastinal and parasternal dullness, spinal and paravertebral dullness, vertebral bronchophony below the seventh cervical vertebra, venous hum over the manubrium when the head is hyperextended, and râles in the region of the nipple. Much reliance is placed upon x-ray examinations. [F. W. P.]

4. Macfie gives a clear statement of the part played by draughts in producing colds. He concludes that draughts do occasionally play an auxiliary part in the production of colds, but that they are easily to be deprived of their dangers and should be favored rather than feared. If the body and the skin are kept in good condition and living-rooms kept clean, free from dust and cool and well-ventilated, draughts will have no ill effects. [J. B. H.]

JAN. 21, 1911.

1. *JEX-BLAKE, A. J. *A Lecture on Cardiac Arrhythmia.*
2. *BOSANQUET, W. C. *A Lecture on Theory and Practice in the Treatment of Pulmonary Tuberculosis.*
3. *CROWE, H. W. *A Series of One Thousand Inoculations, Chiefly in Private Practice.*
4. *MILLS, J. A. *Typhoid Infection.*
5. SYMES, J. O. *Myasthenia with Enlargement of the Thymus Gland.*
6. GUNN, J. A., AND FELTHAM, W. J. *The Antihemolytic Action of Arsenic.*

1. Jex-Blake, in a lecture on cardiac arrhythmia, gives a clear and concise résumé of this somewhat difficult and complex subject. He classifies the subject as follows as to causes: (1) Those causes arising within the heart and due to changes in the state of nutrition of its walls; and (2) those causes arising outside the heart, due to alterations in nervous impulses or to changes in the case with which the blood enters or leaves it. After discussing the physiology of the heart beat, he takes up the extra-cardiac causes of irregularity: (*a*) respiratory; (*b*) neurogenic, due to emotions, toxins such as alcohol, tea, tobacco; and (*c*) vascular causes, such as adhesions and other rare conditions. Under the intracardiac causes he discusses heart block and paroxysmal tachycardia. The article is well worth reading.

2. Bosanquet gives an excellent general review of the treatment of pulmonary tuberculosis. He does not think estimation of the opsonic index a necessary procedure. Under forced feeding, he calls attention to the fact that it is what the stomach can digest rather than what it can hold which is of value. His ideas as to the use of alcohol and tobacco are eminently sane. He does not believe in the value of putting on fat alone. "A consumptive may be fat and yet be going down hill." He emphasizes the value of work treatment, yet urges saneness in its use; temperature charts alone are not a safe guide. He urges sanatorium treatment as an educational measure. His ideas on the value of climate in treatment are excellent. The paper contains many valuable suggestions.

3. Crowe describes his results with the vaccine treatment of various conditions. His figures are too small to judge from but are none the less interesting. In tuberculosis he has had poor results in kidney cases, and good results in peritoneum cases. He believes that autoinoculation by regulated massage is a better treatment of tuberculous glands than injections of tuberculin. (This, unless the patient was under very close supervision, would hardly accord with our views. — J. B. H.)

4. Mills believes that rats are an important factor as carriers of typhoid infection and cites cases to demonstrate his theory. [J. B. H.]

2. These authors have succeeded in producing a disease in rabbits which they consider without doubt to be a true syphilitic infection. They have succeeded in recovering the spirochete from the blood in some cases. They think that this experimental work will open up a large field for solving questions of heredity, the relation of diseases of the nervous system and methods of treatment by chemotherapy.

5. Boas reports a test for occult blood in the stools with phenolphthalein as the reagent. He thinks it stands between the guaiac and the benzidin test in sensitiveness. This reagent has the advantage of being more readily preserved in the solution in which it is used. [C. F., JR.]

14. MEIROWSKY, E. *The Technic of Intravenous Injection.*

2. Waldvogel thinks that gastrospasm is much commoner as a motor neurosis independent of organic disease of the stomach than is generally supposed. He finds it in neurasthenic states, in lead colic, in arteriosclerosis of the abdominal vessels and after abuse of tobacco. Excess of HCl is generally associated with it. The symptoms are a sense of oppression or fullness in the epigastrium, the belching of gas without odor, and pain in the absence of evidence of stasis of food or palpable tumor. He claims to have had prompt and good results from the use of atropine in the dose of 0.0005 gm. twice daily. He gives no statistics of cases.

3. The writer describes a new reaction by which he believes that serum sickness can be accurately diagnosed. The test is performed by mixing washed horse corpuscles with serum of the patient in different dilutions. A positive reaction is shown by agglutination of the corpuscles into masses which can be seen with the naked eye. [G. C. S.]

5. MARQUIS, M. E. *Origin of Hypertrophy of the Prostate.*

1. Beck reports the results of the employment of his bismuth paste in the treatment of tuberculous abscesses at the North Chicago Hospital. He believes that its favorable action is based, not on the antiseptic power of the bismuth, but on the fundamental principle which governs all modify-

ing substances, namely, the production of local leucocytosis by chemiotaxis.

3. Tanton reports 2 cases of isolated fracture of transverse processes of the vertebræ, and collects 17 others from the literature. [R. M. G.]

## Obituaries.

### EDWARD G. JANEWAY, M.D.

Dr. Edward Gamaliel Janeway, of New York, one of the most eminent physicians in this country, died at his country home in Summit, N. J., on Feb. 10. He had been in poor health for some months, but his acute illness was of but a few days' duration. He was a son of the late Dr. George J. Janeway, and was born in Middlesex County, New Jersey, on Aug. 21, 1841. He was graduated from Rutgers College, New Brunswick, in 1860, and from the College of Physicians and Surgeons, New York, in 1864. Before receiving his degree he served in 1862–63 as a medical cadet in the United States Army Hospital, at Newark, N. J. In 1866 he was appointed curator to Bellevue Hospital, a position which he held until 1872, when he was made a visiting physician to the hospital; while from 1868 to 1871 he was visiting physician to Charity Hospital on Blackwell's Island, now the City Hospital. He very early won distinction in the profession, especially on account of his skill as a pathologist. In 1872 he was appointed professor of pathological and practical anatomy in Bellevue Hospital Medical College, and, in addition, lecturer on materia medica, therapeutics and clinical medicine. In 1881 he became professor of diseases of the mind and nervous system in the same school, and on the death of Dr. Austin Flint, Sr., in 1886, succeeded him as professor of the principles and practice of medicine and clinical medicine. He afterwards occupied the same chair in the University and Bellevue Hospital Medical College, after the union of the two schools, and in 1898 was made dean of the faculty, a position which he held until 1905. The degree of LL.D. was conferred upon him by Columbia and Princeton universities and Rutgers College. He was at different times president of the New York Pathological Society, the New York Academy of Medicine, and the National Association for the Study and Prevention of Tuberculosis, and he was one of the founders of the New York State and County Medical Associations. From 1875 to 1881 he was a commissioner in the Health Department, and in 1892, when the city was threatened with an invasion of cholera, he was a member of the advisory committee of the New York Chamber of Commerce. He was the author of a valuable work on the clinical diagnosis of hepatic affections, and his "Pathological Reports of Autopsies made in Bellevue Hospital" constituted a rich thesaurus of information.

Dr. Janeway's exceptional ability as a diagnostician, as well as his resourcefulness in therapeutic measures, gave him pre-eminence as a consultant, and until the end of his life his services in this capacity were eagerly sought for. His manner of dealing with his fellow practitioners and with patients was characterized by great simplicity and directness, and this was also true of his teaching, in which field his reputation was deservedly of the highest. At the time of his death he was consulting physician to Bellevue, St. Luke's, the Presbyterian, Mount Sinai, and various other hospitals. He is survived by a widow, who was the daughter of the late E. P. Rogers, D.D., two married daughters, and a son, Dr. Theodore Janeway, who also is widely known in the medical profession.

### LEONARD P. KINNICUTT, Sc.D.

Leonard Parker Kinnicutt, Sc.D., who died of tuberculosis on Feb. 6, at Worcester, Mass., was born in that city on May 22, 1854. He took the course in chemistry at the Massachusetts Institute of Technology, and in 1875 graduated with the degree of Sc.B. During the next four years he studied at the Universities of Bonn and Heidelberg in Germany, and returning thence in 1879 worked for a year at Johns Hopkins, and subsequently for two years at Harvard, from which he received the degree of Sc.D. in 1882. He was instructor in chemistry at Harvard from 1880 to 1883. In the latter year he was appointed assistant professor and in 1885 professor of chemistry at the Worcester Polytechnic Institute, and in 1890 became director of its chemical laboratory. Since 1903 he had been consulting chemist of the Connecticut Sewerage Commission. He was a Fellow and former vice-president of the American Academy for the Advancement of Science, a Fellow of the American Academy of Arts and Sciences and of the London Chemical Society; he was a member of the American Chemical Society, of the Society of Chemical Industry, of the Society of American Bacteriologists, and of the Deutsche Chemische Gesellschaft.

Professor Kinnicutt was an expert in sanitary chemistry, especially in the disposal of sewage, and his reputation was not merely local or national, but international. His latest book, "Sewage Disposal," written in conjunction with Professor Winslow, of the Institute of Technology, and Mr. Pratt, of the Ohio State Board of Health, is a complete treatise on the chemical, biologic and engineering aspects of this great problem of civilization, and promises to become an English classic on the subject.

In spite of disease, his life was one of tireless, active and extensive labor in the service of science and of the community. He was a pioneer and an authority in a field of work which has done so much for the advancement of preventive medicine. Of his personality, Prof. William T. Sedgwick has written:

"He was unique, lovable and altogether charming. Kindness and friendship such as his life exemplified could not further go. He was critical, yet just; fearless, yet considerate of others; honest to a fault; a hard worker; and to a degree nowadays unusual an accomplished and cultivated gentleman."

## Miscellany.

### PROGRESS OF THE PLAGUE IN CHINA.

REPORTS indicate that during the past week the epidemic of bubonic plague in China has been steadily progressing. At Harbin there is said to be some decrease in the number of cases, but the infection which has spread thence is now rife in many surrounding cities. At Assikko, in Manchuria, the daily average of deaths from plague is said to be nearly four hundred. Report from St. Petersburg states that there are one hundred deaths daily in Kwanchengtze, a large town west of the province of Kirin, on the line of the Manchurian railway. Forty-nine deaths were reported to have occurred at Tsitsikar on Feb. 5; there are said to be fifteen deaths daily at Tientsin; and a report to Washington, D. C., from the United States consul at Chefoo, China, states that two hundred deaths have already occurred at that port, and that there are now twenty deaths there daily from the disease. The German government has taken most rigid measures to keep the plague out of its protectorate of Kiao Chow and has established complete military quarantine of the town of Tsingtau. The Japanese government has sent Dr. S. Kitasato to Manchuria to investigate and report on the situation; and the United States has detailed for the same purpose, as representative of the American National Red Cross Society, Dr. Richard P. Strong, now stationed at Manila, P. I., as chief of the biological laboratory of the Philippine Bureau of Science.

### SOCIETY NOTICES.

NEW ENGLAND PEDIATRIC SOCIETY. — The fourteenth meeting will be held in Sprague Hall, Boston Medical Library, 8 The Fenway, on Saturday, Feb. 25, at 8.15 P.M. The following papers will be read: (1) "The Transfusion of Infants with Glass Tubes," Beth Vincent, M.D., Boston. (2) "Public Health Laboratory," B. L. Arms, M.D., Boston, director of the City Bacteriological Laboratory. (3) "Diarrhea in Infants Associated with the Presence of the Gas Bacillus in the Stools," Arthur I. Kendall, Ph.D., Boston, Richard M. Smith, M.D., Boston. Light refreshments will be served after the meeting.

JOHN LOVETT MORSE, M.D., *President.* FRITZ B. TALBOT, M.D., *Secretary.*

THE BOSTON SOCIETY OF MEDICAL SCIENCES. — The next meeting will be held at the Harvard Medical School, in the amphitheater of Building D, on Tuesday, Feb. 21, 1911, at 8.15 P.M. Papers will be presented by Drs. W. B. Cannon and D. de la Paz: "The Stimulation of Adrenal Secretion by Emotional Excitement." (20 minutes.) Dr. R. C. Larrabee: "Carnot's Hæmopoietic Serum." (15 minutes.) Drs. W. P. Lucas and R. B. Osgood: "Experimental Reproduction of Anterior Poliomyelitis from the Nasal Mucosa of Recovered Monkeys." (15 minutes.)

CLEAVELAND FLOYD, M.D., *Secretary.*

### RECENT DEATHS.

DR. WHITFIELD WARD, of New York, died on Feb. 8. He was born in New York City on July 28, 1850, and was an alumnus of Columbia University. He was graduated from Bellevue Hospital Medical College in 1874.

DR. HORACE W. PATTERSON, a prominent physician of New Brighton, Staten Island, N. Y., died on Feb. 6, in the S. R. Smith Infirmary. He was forty years of age, and was graduated from the College of Physicians and Surgeons, New York, in 1895. At the time of his death he was chief of the Division of Communicable Diseases of the New York Health Department in the Borough of Richmond, pathologist to the S. R. Smith Infirmary, and attending physician to St. Vincent's Sanitarium for Tuberculosis.

DR. ROBERT HAMILTON PHELPS, of Norwich, Chenango County, N. Y., died on Feb. 6, aged forty-one years. He was graduated from the medical department of Syracuse University in 1894.

## Original Articles.

### A REVIEW OF THE MIDWIFE SITUATION.*

BY ARTHUR BREWSTER EMMONS, 2D, M.D., BOSTON,
AND
JAMES LINCOLN HUNTINGTON, M.D., BOSTON.

THE midwife situation abroad and in our own country has impressed us so strongly that, when the question of licensing the midwife was agitated, we felt that the subject merited a thorough study in order to form an opinion which might command the consideration and respect of the best medical thought of this country. We hope for your co-operation in this study, and, therefore, do not hesitate to go into considerable detail on what seem to us points of great importance.

Let us begin by reviewing the methods of supervision employed in foreign countries and our own. Then let us carefully consider whether or not we have the moral right, in view of our present knowledge, to offer to the community two standards of obstetrical skill: one for those who can afford it, — the product of four years of medical training; the other for the impecunious, — the midwife, unskilled in general medicine and surgical technic. Or let us see if it is not possible to have our present laws in Massachusetts enforced and one grade of obstetrical knowledge required for all who practice the art.

To realize that this is not an idle theoretical discussion, but the presentation of an actual problem directly concerning the welfare of our community, we only have to consult the proceedings of two committees [1, 2] interested in social service here in Massachusetts to find that proposed legislation for the immediate regulation and licensing of midwives has been actually agitated during this present year.

We hope to convince you that the practice of the midwife, when licensed, has never been successfully or satisfactorily regulated and controlled in any country or state; moreover, that we in Massachusetts are most favorably situated in this regard both as to the number of midwives actually in practice now and in the existing laws concerning them. Also we hope to show that these laws can be so modified as to greatly facilitate the prosecutions not only of the midwives, who practice now in open violation of the law, but also the class of practitioners that shield these women. We also hope to show that the community should be aroused to demand and expect much better obstetric service than it would be possible for the people to receive under the midwife, no matter how well trained for her vocation.

*Historical.* — The midwife problem in its broad sense is a sociological problem. To understand clearly our present position, a brief glimpse at the past, tracing the midwife in her development and course, may give us perspective and a broader view of the present situation. In Great Britain and throughout Europe the midwife has been an established institution in all historic time.

Bacteriology, antiseptic and aseptic surgery have put obstetrics on an entirely different basis, raising it to the position, sociologically at least, of the most important branch of surgery. Therefore it is right that society demand the most intelligent obstetric care. These conditions have developed the efficient trained nurse of to-day, acting in harmony with the doctor, who carries the responsibility. What position, then, does the midwife hold in this modern scheme?

We shall attempt to answer this question by showing what has been done in the older countries, where the best efforts for her development have been made, and also the provisions for her training in this country, and with what results.

A glance at the most recent history in Europe and at home shows a series of attempts to license, educate and control the midwife. The writers have recently had the opportunity personally to observe the conditions in England, Austria, France and Germany, and to ascertain the laws of Italy in regard to the midwife. We find that the question of reducing to a fair minimum the injuries to her patients is a more or less urgent question in every country, including many of our states to-day.

#### ITALY.

A joint committee of the Chicago Medical Society and the Hull House,[3] after an investigation of the midwife situation throughout the world, gave it as their opinion that the best schools of midwives were those of Rome and Naples, with Paris third and Berlin fourth.

In 1886 the Italian government [4] took control of the midwife situation. Since that time reliable statistics as to puerperal fever and other diseases related to the parturient woman have been collected. Before this took place the mortality was admittedly very high.

A new law was put in force Feb. 23, 1890, and has remained substantially the same since that date. Under this law the education of the midwife was placed under the supervision of the government. Midwife schools could be established in any city or town where a university existed. The funds were to be supplied by the Minister of Instruction in conjunction with the local authorities. The direction and teaching were to be under the professor of obstetrics.

The requirements for admission to such a school were as follows: The candidate must be healthy, not disfigured, between the ages of eighteen and thirty-six. She must present a certificate of good conduct and have been successfully vaccinated or have had smallpox. The total fees were $38. The course was from one and one-third to two years. The examinations were both written and oral, with graded marks. One of the requirements was the histories and clinical courses of two complete cases observed by the candidate and signed by the professor. If "eminence" was attained, the matriculation fee and one year's tuition was returned to the candidate.

*Regulations of practice.* — The midwife must notify a physician if the patient's temperature reaches 100.4°. If a physician is not available, and the temperature rises to 101.3°, the municipal

* Read before the Obstetrical Society of Boston, Dec. 27, 1910.

authorities must be notified. She is prohibited from using instruments or drugs or doing intrauterine operations, except in urgent cases, where she assumes the responsibility of her actions. If puerperal fever develops, she is suspended for five days or disinfected by the authorities. She must keep a case book.

*Instructions.* — Her instructions are minute and in general good, describing a fair technic and the ordinary care of a labor case, which if carefully and conscientiously carried out by intelligent women should maintain a fairly satisfactory mortality rate. Let us glance for a moment at the results of this system.

Statistics collected in 1894 for the previous fifteen years show the conditions from the time the government took control, three years before the present law went into effect, and the twelve years following. Briefly, these figures show that in 1887 there were 85 deaths per million population from puerperal fever. A drop to 56 took place after the law of 1890 came into effect, and a gradual falling continued from that time till in 1902 there were 32 deaths from puerperal fever per million inhabitants. Similarly in other diseases connected with pregnancy, parturition and the puerperium the deaths fell between 1887 and 1902 from 150 to 53 per million population.

As the midwife does the bulk of obstetrics in Italy, the improvement in her training and equipment must constitute a large factor in this better showing.

The total death-rate, however, for 1902 was 1,037 from puerperal fever, and from other diseases connected with pregnancy was 1,746, giving a combined death toll from the practice of the midwives for that year of 2,783, with an estimated population of about 33,000,000, or 85 per million, and this rate of preventable deaths after the law has been in force twelve years and may be said to be in good working order.

### FRANCE.[5]

Since 1803 the midwife has been controlled in France. The French laws of 1893 require a theoretical and practical course of two years in order to obtain a midwife's diploma issued by the government.

### AUSTRIA.[6, 7]

In 1891, Austria lengthened the midwife course from six months to two years in the clinic, six months' preliminary theoretical and eighteen months' practical work.

### GERMANY.

In Germany we find essentially the same condition as in Austria, and as we have had opportunity to observe the entire training of the midwife, and the results of her practice, we propose to discuss at length the details of the situation of the German midwife, feeling that a study of her position will reveal not only the amount of knowledge required before she is entrusted with responsibility, but also the complicated and complete supervision regarded as essential by that enlightened nation. Such a study will enable us to see what preparations we must be ready to make should we decide to adopt a system with the midwife as the solution of our present condition, and what results we are entitled to expect under practically ideal supervision.

We have been unable to learn exactly how much obstetrics in Germany is in the hands of the midwife. Certainly nearly all normal cases and most operative cases in the early part of labor are conducted by the midwife alone, save in the families of wealth and position, where education has opened their eyes to the necessity for the physician's exclusive help during this critical period. We were constantly surprised to see how even in many of the families of the well-to-do the midwife was depended upon to assume the full responsibility. In the type of women entering the schools of midwifery, nearly all classes were represented, from the professor's daughter to the simplest peasant girl.

We must realize that Germany has been training the midwife for generations to understand the firmness of her hold upon the general public. The trained midwife followed as naturally in the course of development as the trained physician, and we find with the knowledge of the necessity for clean obstetrics, stringent laws were passed for her education and regulation.

The midwife in Germany to-day is trained in the government *kliniks* by university professors who are salaried by the state — the same professors, for the most part, who are responsible for the education of the medical students. The midwife course is in most cases six months; always as much as that is required. Her textbook, issued by the government, she is required to know almost by heart from cover to cover. It takes up anatomy, including the entire skeleton; the nervous, alimentary and circulatory systems, as well as the genito-urinary tract. There is also considerable physiology, bacteriology, normal and pathological obstetrics, and a full description of her legal status. This book is supplemented by lectures and explained by recitations occupying in all about twelve hours a week throughout the course.

She also has thorough drills in the principles of diagnosis by means of abdominal palpation, auscultation, pelvimetry and vaginal examination, this work being carried on in the pregnancy wards. She has almost daily drill in the "vaginal touch" by means of the manniken and the fetal cadaver. She is required to make vaginal examinations and to deliver a certain number of cases in the confinement ward under the direction of the resident physician and graduate midwives. Here also she is taught as far as is possible in the limited time of her instruction the principles of aseptic technic. This is further supplemented by the observation of surgical operations, both gynecological and obstetrical, in the amphitheater.

At the conclusion of her course she is subjected to a rigid examination, both oral and written, before a board of examiners. Besides answering questions for some fifteen minutes, the candidate

must demonstrate her knowledge of making a diagnosis of presentation and position in the manniken, and outlining her methods of procedure in the given case. As we were present at such an examination we can definitely state that it is a rigid test and one that the average third-year student of the Harvard Medical School would find some difficulty in passing with distinction.

Now let us turn to the midwife in practice and see what her position is; in other words, how she is regulated. She is constantly under the supervision of a government physician, who is coroner, medical examiner and local board of health officer combined. She must report to him before she begins her practice, and so long as she is in his jurisdiction her work is constantly subjected to his supervision. To him she must report immediately all stillbirths and deaths, all cases of puerperal fever and ophthalmia neonatorum. Her home, her equipment, her clothing and her person must always be ready for his inspection. She may lose her right to practice if her home is dirty or if she is caring for obstetrical cases under her own roof. The contents of her bag and her case book are outlined by law. She is required to wear clean and washable gowns when in attendance on cases. Her hands must be clean and the skin in good condition at all times. She must report to this officer any septic lesion or ulcer on any part of her body. Violations of these rules will lead to fine, or imprisonment, or both.

The midwife must report to some local physician any symptoms suggesting eclampsia or miscarriage. She must notify him in any case of antepartum hemorrhage, contracted pelvis or abnormal presentation, and this includes a breech presentation. Should the second stage last more than two hours, without progress; should the pulse or temperature rise above the limit considered not abnormal in obstetrics; the fetal heart rise above 180 or fall below 110; the placenta remain in the uterus too long after the delivery of the child; the uterus fail to contract and continue to bleed; or the perineum rupture during delivery, the midwife must notify a physician in writing, or over the telephone, of the condition, and unless actually employed on some case requiring his time it shall be the duty of this physician to respond immediately to the midwife's summons or he is subject to punishment.

In case an emergency arises out of her jurisdiction as laid down by law, after notifying the physician (or even before if the danger is imminent), it shall be her duty to do whatever seems necessary for her to perform, save only forceps and version, but in each and every instance she must communicate as soon as possible with the health officer by a detailed account of exactly what she has done and her reasons for so doing.

This gives an idea of the duties and responsibilities laid down by law for the regulation of the midwife. Added to all these requirements she must also return at stated intervals, in Bavaria every two years, for re-examination, after a few days' residence in the *klinik*, thus obliging her to keep constantly up to date.

But let us see how, in spite of all this, the midwife actually appears in practice in Germany. In the first place, one observing the work of the midwife in the confinement wards is struck by her lack of what is known as the aseptic conscience; that is, the knowledge that she is or is not surgically clean. After faithfully scrubbing her hands for the allotted fifteen minutes, she will unconsciously touch something outside of the sterile field and continue as if surgically clean. This, the writers have often observed. Of course there are exceptional pupil midwives who do not fall into this error, and they are usually ones who have previously received a nurse's training. But if the midwife makes these breaks in the hospital under the eyes of her instructor, and in ideal surroundings for surgical cleanliness, how much more likely will she be to fall into careless ways when out alone in a peasant's house? This is very marked in those midwives who return for their required period of training and re-examination. As one German house officer in the Frauenklinik in Munich remarked, "It is utterly impossible to teach these older midwives the first principles of asepsis."

At the time of the examination of the midwives in Professor Stökel's *klinik* in Marburg, one of the writers was present at dinner with the board of examiners, and after the dinner joined in the perfectly free discussion of the midwife problem, for these gentlemen openly admitted that it was a distinct problem to-day in Germany. When informed in answer to a question that it was against the law to practice as a midwife in Massachusetts, two members of the board instantly agreed that we were to be congratulated on our position, and that it was as it should be.

Others felt that while it might be true in America that the midwife could be dispensed with, that it was a mistake to hope for such a thing in Germany. Professor Stökel held this view and felt that the solution of this problem was in raising the standard of the German midwife by requiring a previous training, such as that of a nurse, before undertaking the midwife course. But he admitted that the community as a whole would have to be educated and said that it was a curious fact that even among people of refinement, the older and dirtier the midwife, the greater seemed the confidence placed in her ability and judgment.

Obstetricians as a whole lament the condition in Germany; many admitted frankly that of course the midwife was not qualified to attend cases in labor, but that the system was so firmly established in the community at large that it was doubtful if there ever could be a complete change made. Professor Bumm, in his recent book on obstetrics,[8] admits that the number of deaths from puerperal fever in Germany is far too high, — out of 2,000,000 births, 5,000 deaths from puerperal fever were reported in one year, — and he states that of course many cases were unreported.

A Berlin physician prominent in gynecology has recently written[9] to a committee of the

American Medical Association asking for information in regard to the number of deaths from puerperal fever throughout America, as he understood that we had no midwives in this country. The answer was made that, not only were we without vital statistics of any value, but that we were in many states overrun by midwives. The Department of Medical Economies of the *Journal of the American Medical Association*, referring to this correspondence, adds, "Midwifery is not so well regulated in this country as in Europe, and yet the harm done is probably less, since midwives are not so numerous."

The midwife is responsible for the extreme conservatism in the German point of view in regard to labor. Cases are allowed by the midwife to go along in labor practically indefinitely unless fever or other reportable complication arises. These cases regularly come late to operation, and the trend of obstetrical research has been distinctly how to care for these late emergencies. As a matter of fact, fever is the commonest cause for which the German midwife sends for help. In not a few of these cases, through inability to recognize a contracted pelvis, the only operation to be widely recommended in general practice is craniotomy on the living child, while in the *kliniks* this condition is met by hebeostomy and extraperitoneal Cæsarean section.[10]

Thus we have in Germany a system of training and regulation of the midwife so complete as to be almost ideal — a system of perfect harmony between the midwife and the physician. And yet the system is not a success in so far as it fails to meet with the approval of those medical scientists most deeply interested in the progress of German obstetrics.

### ENGLAND.

To us in New England the situation in Great Britain is of special interest because we are largely of English stock and are influenced by English tradition. In England from earliest times midwives have flourished and have been an integral factor in the social fabric. The legal correspondent of the *Lancet* gives the following historical sketch:[11]

"Four centuries ago bishops in England licensed the physicians, surgeons and midwives. They continued this practice down to the middle of the eighteenth century. About that time the College of Physicians of London took over the duties from the bishops of examining and admitting midwives to practice, a charge which they in turn renounced some ninety years ago. Since that time any person who chose might undertake the important duties of midwife. No test of competency was imposed by any responsible authority, and so the public was left to such protection as the common law afforded against the malpractice of uninstructed practitioners." For many years prior to the active agitation of the Midwife Law, which culminated in 1902, there were trained midwives acting in conjunction with some of the hospitals and institutions in London.

Since the passage of the Medical Acts, bills have been brought forward every few years in Parliament for licensing and regulating midwives. These bills were usually crushed by medical advice, but while the medical profession never took a definite and organized stand against the idea, the promoters of the bills were gaining in organization and influence with every defeat. In 1900 a measure brought forward by them was nearly made a law and in spite of defeat they continued these activities without pause with the opening of the succeeding session of Parliament.

Let us see who the contending parties were. Mr. Egerton, in a speech in the House of Commons, is our authority [12] for the following forces in favor of the bill for the licensing and regulation of midwives: the Obstetrical Medical Men, Women's National Liberal Association, Women's Industrial Council, Women's Liberal Federation, the Incorporated Midwives Institute and representatives of the Body of Coroners. Whether the reference to the Obstetrical Medical Men means a definite action on the part of the British Obstetrical Society or not, we have been unable to ascertain, but English obstetricians frankly admit that they as a whole were in favor of the act, as they were in constant touch with the evils of the then existing conditions and felt that any change would be welcome. It is interesting to note that many of the other organizations in favor of this measure, and most active in bringing it about, were societies interested in enlarging the sphere of the professional woman. This was an important factor — to give a new field of useful (?) activity to the women of England.

Against the bill we find the majority of the medical profession of England ununited and lacking definite policy. The General Council of Medical Education and Registration considered the bill thoroughly bad. The leading medical journals opposed it. In Parliament one of the opposition stated that 95% of the medical men of England were against the bill. In 1900 the *Lancet* made an extensive canvass [13] of English medical men and found that, out of 7,250, 5,000 opposed the bill, 640 were indifferent and 1,547 were in favor of the measure. Some physicians wrote against the bill in broad, sound terms; others attacked it bitterly on narrow and private grounds, and we actually find a body of medical men urging that all medical practitioners unite in a declination ever to respond to an obstetric case of difficulty or danger when it is known that a midwife has been in attendance.

Fenwick,[14] writing in 1902, emphasizes the fact that midwives are dying out naturally; therefore there is no need of legislation which would lead, he considers, to the following situation: A new order of independent practitioners; the midwife after some three months of work and the expenditure of some $75 would be created by Parliament the equal of the medical practitioner, who has spent five years or more in preparation and, roughly, $5,000. He goes on to say: "It is mere futile foolishness to pretend that she will not enter at once into competition with the

general practitioner, or to imagine that she will carefully confine her attention to the poorer classes, or to expect that she will refrain from practicing medicine as well as midwifery. It is submitted that the first and greatest effect of this legislation will be to flood the country with more or less well-educated women only too eager to avail themselves of the opportunity of becoming licensed quacks." Let us note later how nearly his prophecy has come true.

Another objection was made to the Midwife Law.[15] As drafted, it applied only to England and Wales. One member of Parliament proposed that the new law should conform with the provision in Ireland, where an almost perfect midwife system was in force. In 1902, that country was divided into well-arranged dispensary districts, and in each district a medical man with a midwife under him. The midwife cannot act herself, but was sent by the physician and kept him informed of the progress of the case, and of any complications. This proposal, however, met with no response.

This futile and diversified opposition by the ununited medical profession of England met with the expected defeat, and the bill was made a law July 30, 1902. Briefly condensed,[16] it prohibited any woman after a lapse of a few years from using the name of midwife or its equivalent, or to habitually and for gain attend women in childbirth unless certified to do so by the Central Midwives' Board, violation of this to be punished by fine. It placed all authority in the hands of a Central Midwives' Board composed of seven persons, four to be medical practitioners appointed by medical bodies of recognized standing. Of the other three, one at least must be a woman. This board was to act under the approval of the Privy Council and after consultation with the General Medical Council. It defines[17] the most essential requirements for the midwife as: The obstetrical examination, external and vaginal; the delivery of 20 lying-in women under competent supervision, and the following of an equal number of women during the ten days after labor; the candidate must have attended a sufficient course of instruction of not less than three months' duration, and passed a satisfactory examination.

We now see the legal status of the midwife in England to-day. She has a short course of training in any one of the leading lying-in hospitals in England instructed by members of the staff, who are also the professors in the medical schools. This is more or less at the expense of the medical students, who formerly enjoyed more of the professors' time than now.

Let us see how the law has worked out. There are at the present time[18] 29,000 midwives on the roll of the Central Midwives' Board, nearly as many as there are physicians in Great Britain. Thus we find that practically all of the prophetic statements of our authority Fenwick have been fulfilled. We have the statements of two prominent obstetricians in London to the effect that the midwives to-day are doing the bulk of the middle-class obstetrics in England, and not only that, but they are taking care of the children during the first year as practicing physicians. There is also a general complaint among the practitioners that humanity compels them to respond to the summons of the midwife when in trouble, but there is no provision for any compensation for the physician.[19]

So we have in England two standards of obstetrics side by side, but not in harmony. We have a midwife scantily trained assuming the rôle of physician not only within but outside her legal province. That such a profession is remunerative must be admitted when we see the tremendous size to which it has grown, and when we realize that it is increasing much faster than is the medical profession. With such inadequate training and such meager provision made for supervision, working utterly out of harmony with a growing proportion of the medical profession, we can feel certain that the results must be inferior to what we have seen in Italy and Germany.

### UNITED STATES.

In the United States we have at the start one distinct advantage over the older European countries. Although the midwife custom or tradition came over with the early settlers, it was soon shaken off. Let us quote one physician in this Commonwealth, who writes anonymously in 1820,[20] presupposing evidently an agitation of the midwife situation: "The attention of the public having been lately turned to the subject of the employment of female accoucheurs, has led to some discussion among the faculty and others with regard to the safety and expediency of introducing them into the practice of midwifery instead of physicians. There is, perhaps, no place of equal size in which this branch of medical practice has been so entirely confined to male practitioners as in this town [Boston]. In no place perhaps in the world is this standard higher, in no place is the female character more pure and elevated than in this; yet in no place probably is the practice of midwifery more safe."

"No one can thoroughly understand the nature and treatment of labor who does not understand thoroughly the profession of medicine as a whole. He must look upon it with the eye of a physiologist and a physician before he can comprehend its nature, its relations, or its objects."

Again I quote our physician of 1820, long before the days of asepsis and modern surgical obstetrics. He continues: "As medical science has improved, it seems at last to have been settled that physicians regularly educated could alone be adequate to the exigences of obstetric practice. This is the opinion held, taught and defended by the most eminent lecturers on midwifery in Europe.

"The opinion in Great Britain of the profession at large has been expressed in the most unqualified manner. Among ourselves, it is scarcely more than half a century since females were almost the only accoucheurs. It was one of the first and happiest fruits of improved medical

education in America that they were excluded from the practice; and it was only by the united and persevering exertions of some of the most distinguished individuals of which our profession has been able to boast, that this was effected."

After enumerating various emergencies which might arise with or without the midwife's knowledge, and for which the physician is hastily summoned, for the physician in all countries is the last resort, our writer of nearly a century ago says: "No man called in on an emergency like those I have mentioned can be made sufficiently master of the circumstances to be able at once to do justice to himself or to the patient. Much depends always upon the previous history of the case, the course which the labor has taken, the symptoms which have occurred in the course of it. A moment of hurry and of danger like this, when the fear of a fatal issue is the only object before the eyes of the patient, her friends or her attendant, is no time for the communication of a long series of facts, no time to enter into the whole details of the labor. And besides this, none but the accoucheur herself is a competent judge when the assistance of a consultation is required, and she will very naturally be desirous to put off as long as possible the moment when she is to acknowledge herself incompetent to the further management of the case."

In conclusion, our far-seeing friend of 1820 writes: "It is now to be determined whether, when the most rapid advances are making in learning and knowledge, when new opportunities are opening for the improvement and cultivation of medical science, when the members of the profession are becoming better educated and better fitted for its duties, society will choose to go back for half a century and adopt a practice which experience has shown to be unsafe and pernicious."

After ninety years we of the medical profession whose especial duty it is to protect the welfare of the hopeful mother and her unborn child are brought to face the same problem. Shall we who enjoy the many improvements in medical science, who are "better educated and fitted for its duties," who enjoy "the advances in learning and knowledge," and who realize much more fully than our wise and loyal medical predecessor of nearly a century ago possibly could realize the responsibilities of the more intricate, the more complex and the more difficult methods required by modern obstetrics, and who look forward to far greater advances in preventive obstetrics, whereby the skill and judgment of the obstetrician shall be trained to foresee and forestall the many dangers to the coming mother; shall we, I say, let down the bars, shall we take the weaker course and compromise the birthright bequeathed to us by such worthies?

But to return to our history. What influences in society have again raised this question, and what new arguments do they bring?

With the stream, or, better, the mighty river of emigration which has swept into this country within the last half century, has come very naturally the midwife-habit and the midwife. In all the large cities or centers of foreign population these midwives have quietly plied their trade, commonly unrestricted, unsupervised and unmolested.

Not till the present wave of prophylactic medicine with its searchings for the causes of disease, be they pathological, social or criminal, did the midwife come strongly into official light. The investigation of infant mortality, ophthalmia neonatorum, of puerperal fever and finally of abortion, have pointed a finger at the midwife as a large factor in the etiology of all these misfortunes. I hasten to add that the midwife is not the only offender. A certain percentage of registered, though ill-equipped, physicians undoubtedly plays a large part in these generally preventable misfortunes, and we feel that any measures undertaken for the improvement of obstetrics in this state should take into consideration both classes of offenders.

The forces now at work uprooting this ancient question are those of the modern efficient charity organization demanding the uplift of the poor, demanding the care for the mother and child; they are the irresistable forces of humanity and right, and we welcome them as friends. We believe it is through such forces, in co-operation with the medical profession, that our best hopes for improved obstetrics lie. But we feel sure that when the situation is clear, intelligent treatment will be sought by other means than the midwife. We agree with the committees of these organizations, who are wisely allied with experienced men of our profession, that the first step, as in any sociological problem, is to obtain full information as to the present abuses and dangers to which the poor lying-in patient may be subjected. Investigation and discussion must precede intelligent action.

Let us first see what our sister states have done in this regard, and with what results. It seems worth while to go into considerable detail in one state so that we may have a standard to which we may compare other states.

### *Illinois.*

We have selected Illinois as a favorable example of the attempts in America to license, control and regulate the midwife.

Before 1899 there was no official recognition of the midwife, a situation by no means uncommon in the United States to-day.

The Act of 1899 licensed midwives in Illinois, and required registration, but made no provisions for supervision, education or control. After a few years under this law a Committee on Criminal Abortion was appointed by the Council of the Chicago Medical Society. This worked with partial success, aiding the police in prosecutions, procuring the removal of advertisements from the press by moral suasion and with the co-operation of the postal authorities.

They soon found that abortion by midwives was very common and that the midwives as a class were deficient in knowledge and ability.

Inquests showed that they practiced medicine and that they cared for abortions and miscarriages, while the law limited their powers to the care of full-term normal labor. As a result of the information obtained by this abortion committee, a joint committee on midwives was formed of members from the Chicago Medical Society and the Hull House, and an investigation instituted, with the result that in 1908 the careful report of a paid investigator was published.[21]

This report states "that the laws governing the practice of midwifery are utterly absurd and inadequate, as is evident when compared with the requirements for obstetric practice by doctors of medicine." A striking contrast is drawn between the training of the medical student with the requirements of a midwife. The report shows careful, thorough and accurate work as far as such an investigation could well go. A trained nurse interviewed 223 midwives, and a woman detective saw as many of these as possible. Card blanks were filled out for each midwife. It was estimated that between 500 and 600 midwives were practicing in Chicago. Of the 223 midwives visited, only 9% were properly registered; 47% of all births in Chicago were reported by midwives.

Only 81 of the midwives were able to read and write English, while 103 could read and write their native language only. One could not read or write her own language; 168 could speak English, while 29 could not; 74 were dependent upon their practice for a livelihood, while 107 were not; 138 lived in good homes and were neatly dressed; 36 were only fair in this regard and 19 were distinctly bad. Of these 223 midwives, 10% were willing to conduct abnormal cases, dilating on their ability to perform version, to deliver a breech or transverse presentation, to remove an adherent placenta or stop a postpartum hemorrhage. The detectives found that 49 agreed to do abortions; 19 received patients into their homes contrary to law, and these homes were practically abortion shops. One, with a policeman husband, leading a dissolute life, showed proudly her license to practice from the State Board; another midwife, while she refused to do an abortion herself, introduced the detective to her physician husband, who agreed to sell her a drug for $3.00 which was guaranteed to bring on an abortion.

Sixty-seven of these midwives held diplomas from foreign schools for midwifery; 111 from schools in America, while 6 held no diplomas. Seven of these American schools in Chicago were investigated. They were veritable diploma mills. The time required for the course was six months, and the fee from $100 to $175. There were three or four hours of instruction weekly. In two of the schools no textbook was used. Thus without being able to read or write, a diploma could be obtained. No practical experience was required by the law in Illinois, although some of these schools furnished it when possible. These 111 American diplomas merely show, then, that these midwives had the money to pay.

One physician in charge of a popular school in Chicago from which many diplomas were seen, offered for an additional fee to instruct the supposed candidate privately in the *modus operandi* of successful abortion work, telling her that it would bring her in large returns, that it was a perfectly safe venture and that the midwives who were caught were fools. Collusion between midwives and physicians for abortions were found, the responsibility and the spoils being divided. An Italian midwife on a labor case informed the ignorant, unsuspecting patient that complications had arisen and called a certain physician who was her accomplice. He operated on a normal case, charged the maximum fee and divided with the midwife.

The investigator closed her report by saying that the most important duty of the state, after examining and licensing the midwife, was to regulate and uplift her, and thus protect the ignorant, credulous community.

The conclusions of the committee of the Chicago Medical Society were that the Illinois law gives no power to inspect and control midwives. They suggest as remediable measures:

1. A short-term license to be issued, thus requiring relicensing at frequent intervals.
2. That a representative of the State Board of Health with the necessary assistants and inspectors be charged with the condition of the midwife practice.
3. That the State Board of Health should make the necessary rules to govern the practice.
4. That the State Board of Health must have control of the education of the midwife, recognizing only the midwife schools of proper standing. Repetition courses every two to four years, with sessions of two to four weeks, should be required.

Thus we have in Illinois a condition of affairs perhaps worse, save only in numbers, than England before the Law of 1902. Can Illinois by these proposed laws hope to approach the situation in Germany?

### *Michigan.*[22]

In Michigan, over 12% of all births for the first three months in 1908 were conducted by midwives. In Detroit many had signs in front of their houses, and all claimed without exception to take complete charge of normal obstetrical cases without a physician. All were foreigners in Detroit: Bohemians, Poles, Germans and Russians, some unable to speak English. Thus we see a condition, without going into further details, closely resembling the situation in Chicago. However, the law in Michigan does not recognize the midwives, and there is no system for their licensing and regulation.

Ohio, Indiana and Wisconsin all have laws for examination and licensing the midwives.

### *New York.*

Coming nearer home, let us glance briefly at the situation in New York state. For many years there has been special legislation regulating the practice of midwives in five of the western

counties. These laws, however, have not been enforced and the situation there has been quite as bad as what we have found in the states of the Middle West.

In 1907 the New York branch of the Health Defense League made an extensive investigation of the situation of the midwife in New York.[23] This investigation revealed the fact that in New York City there were over five hundred midwives practicing in a way similar to what we have reported in Chicago. There were also four midwife schools in New York City. These schools were as thoroughly bad as the ones we have already described.

As a result of this investigation, a midwife law was passed in June, 1907, investing the Department of Health of the City of New York with power and authority to adopt rules and regulations governing the practice of midwifery in New York City. As a result of this law the Department of Health has adopted and published a book of rules governing the practice of the midwife.[24]

Under these rules no person other than a duly authorized physician shall engage in the practice of midwifery without a permit from the Board of Health. To obtain such a permit, an application must be made, certified to by two regularly licensed and registered physicians, and by one reputable and responsible layman. The applicant must be twenty-one years of age, or over, and of moral character; she must be able to read and write; she must have attended, under the instruction of a physician, at least twenty cases of labor, and have had the care of at least twenty mothers and newborn infants during the lying-in period (ten days). This permit to practice is good for one year only, and must be renewed at the end of that time. The Board of Health has the power at any time to revoke this permit. Before a permit is given, the applicant must appear in person at the Department of Health and register her name and address.

In the regulations which she must follow, it is distinctly stated that she is allowed only to attend normal, uncomplicated cases; in all others she must call a physician.

The home of the midwife, her equipment, record of cases and registry of births shall be at all times open to inspection by the authorized officers and agents of the Department of Health. Explicit directions are given for the conduct of normal cases during pregnancy, labor and the puerperium. She is also required to take the temperature morning and night for five days following labor. During this time, or at any later period, should the temperature reach or exceed 101° and continue at this for twenty-four hours, the case must be reported to the Department of Health.

Thus we see some slight provision made for the training of the midwife, no provision made for examination, but excellent rules for her regulation. Exactly how well these laws have been carried out, and with what results, we have been unable to ascertain.

*Maryland.*

Let us briefly trace her history. Before 1894 no restriction or legalization of the midwife is found. Since 1894 there has been a law in Maryland requiring midwives and nurses to report at once to the health officer, or a legally qualified physician, any "mattering or inflammation" about an infant's eyes occurring within two weeks after birth. The midwife was forbidden to use any treatment on her own initiative. From this law five or six convictions have resulted in Baltimore in fourteen years. However, ophthalmia neonatorum was found to be the chief cause of blindness, and 77% of these blind children were born under midwife care and 23% under physicians. With the exception of this law for the control of blindness, the midwife was in no way restricted in Maryland before the present year, 1910.

In 1906 the committee of the Evening Dispensary for working women and girls, in cooperation with the Mothers' Relief Society,[25] found, early in their service, that the conditions of the practice of the midwives in Baltimore city were, in the light of twentieth century medicine, well nigh intolerable. They, therefore, in 1908 employed a trained social worker, who interviewed 150 midwives, with the following resulting report:

First, 40.7% of the births reported at the Board of Health in Baltimore were by midwives.

Second, registration was inadequate.

Third, no qualifications were required for registration of the midwife; 42 had foreign diplomas; 9, American diplomas; 66% gave no evidence of training of any kind; 24.7% could neither read nor write; 16.7% could not speak English.

Fourth, no supervision was provided. There was only the 1894 law providing a penalty for neglect of the infant's eyes. But only 3% of the 150 midwives used a weak solution of nitrate of silver. The remainder used anything from breast milk to bichloride of mercury of unknown strength. Sixty per cent cared for abnormal cases, did versions, removed, manually, delayed placentas. Inspection of their bags showed 41 clean, 51 dirty, 44 had none, a few used antiseptics for the hands and sterilized the tie. The report adds that "on account of lack of supervision, even well-trained midwives take no precautions to insure asepsis." One foreign midwife showed a sterilizing apparatus, required in her native country, the use of which in her adopted country, she said, would expose her to ridicule.

The Medical and Chirurgical Faculty of Maryland,[26] stirred by this report, proposed and backed a bill which was passed by the General Assembly and went into effect July 1, 1910. The Faculty recommended the passage in the following dubious terms, in part: "Midwifery is in many respects the most important branch of the practice of medicine, and hence it seems strangely inconsistent that its legal regulation is far less stringent than that of medical practice in general."

Let us pause a moment to say that it seems to us "strangely inconsistent" that the Medical Faculty of Maryland should make such a statement in furthering a bill to provide legal recognition for a class of practitioners, proved by the report, on which the plea is based, to be far from satisfactory, and often untrustworthy and even criminal. These practitioners are to be allowed to practice midwifery, which the Faculty themselves say "in many respects is the most important branch of the practice of medicine."

The Faculty continue, "There is scarcely a physician in active practice who has not been impressed with the penalties which the women of the state pay for the negligence of the state in throwing proper restrictions about the practice of midwifery; the deaths, the unnecessary invalidism, the preventable blindness." They give the following example: "Some years ago Dr. C. Hampton Jones, Assistant Commissioner of Health in Baltimore city, reported a series of 32 cases of tetanus neonatorum which occurred in Baltimore during one year. Of these, 28 occurred in children less than twenty-one days old, and 12 occurred in the practice of one midwife alone."

Apparently the dread of injuring the few midwives and the fear of failure to secure any legislation outweighed in the minds of the Faculty the dangers of the "penalties which the women and children of the state pay — in deaths, unnecessary invalidism and preventable blindness." They state their attitude thus:

"It must not be assumed that the *medical profession* is bent upon the complete extermination of the race of midwives. Such an assumption would be both unfair and untrue. The profession is convinced that for the present the midwife is to be regarded as *more or less inevitable*, and it also realizes that not all midwives are equally culpable. But, like all other laws, the midwifery act is intended to regulate the midwives who need regulation, rather than those who, in their own limited sphere, may be efficient and conscientious. Of the latter class, it is safe to say that none will have any difficulty in fulfilling the requirements outlined in the bill. Furthermore, it is to be remembered that the law, if enacted, will not affect those midwives now in practice, except to necessitate their re-registration."

Turning now to the law itself, we find provision for the licensing without examination all midwives practicing at the time the law goes into effect. Others registering after that date must undergo an examination by the State Board of Health, requiring at least the ability to read, write and make out correctly a birth certificate. Further, the applicant must present a certificate from a legal practitioner or a maternity hospital that five cases of childbirth have been attended, and that he or she is competent to attend ordinary cases of labor. Such applicant shall also be required to present certificates from three reputable citizens, stating that the applicant is of good moral character.

Perhaps the most interesting clause in this act follows: "It shall be unlawful for any midwife to make a vaginal examination, to attempt to deliver a retained placenta, to attempt to use forceps, to attempt version or any forcible delivery, but such midwife shall, in all cases of labor that are not normal, notify a licensed practitioner of medicine."

No provision is made for the training of the midwife, yet she is required to diagnose the abnormalities of obstetrics, and that without a vaginal examination.

The only redeeming feature which we can find in the law is that the Board of Health can make the examinations of whatever standard they think desirable, and thus can require the same training and knowledge as is required of medical practitioners for similar work. Let us see how the Board of Health uses this power of examination: In November just past, the first test was held. This examination was, however, a test of whether she could read and write English, and little else.

We believe that the Faculty of Medicine of Maryland intended to protect "the women and children of the state from paying" for neglect by deaths, unnecessary invalidism and preventable blindness. How have they succeeded? They have sanctioned and legalized without any test of fitness, or any requirement or means for their education or improvement, all those very women under whom the "well-nigh intolerable" conditions existed, and in our opinion they have provided for and encouraged many more such women for the future, who should make these conditions completely "intolerable." They have perpetuated a system well calculated to *protect the midwife*, who extorts from the women and children of the state the deaths, invalidism and preventable blindness.

### *Massachusetts.*

Let us now turn lastly to the situation, past and present, in Massachusetts. From our cited authority of 1820,[20] as well as from colonial documents, we know that the midwife flourished in the early history of the colonies. Special provisions were made at toll bridges and ferries for the midwife, as well as for the physician, but evidently about 1770 she ceased to play such an important part, at least in the region about Boston. Thus in contra-distinction to the popular supposition, we are here, as in many of the states in the Middle West, dealing, not with a survival, but with an importation, which is the direct result of immigration.

In 1894, in the laws passed for the registration of physicians, there is no mention made of the midwife. Whether intentionally or not, she was thus excluded from the legal practice of her profession. That this law is valid we have ample proof, for she has been prosecuted and convicted of practicing medicine without a license. But, with curious inconsistency, in the law for registration of births, her existence is admitted, and she is allowed to sign these blanks.

The midwife not only exists, but flourishes in

Massachusetts at the present time, in opposition to the law, which we find has been rarely enforced. The Commission for the Blind in a recent investigation has found this to be true. They consider that at the present time about 150 women are practicing midwifery in the state of Massachusetts. They are scattered widely throughout the state, probably some 25 are practicing right here in Boston, although we find that in the past year only 9 have signed birth certificates. They exist also in Lawrence, Lowell, Fall River, Gardner, Ware and New Bedford. Some of these women are apparently doing good obstetrical work; on the other hand, many are quite similar to those we have described in New York and Chicago.

The results of this investigation have led the Commission for the Blind to feel that the situation in Massachusetts is a serious one, and demands alteration. The Women's Municipal League also has encountered the midwife problem in the pioneer work it has been carrying on of caring for its pregnancy clinic. It was through the activities of these two organizations that we became interested in methods for the solution of the existing evil, and through the co-operation of a member of the Commission for the Blind that we were invited to read this paper to-night.

### LEGAL SITUATION.

Before taking up possible means of improving the situation in Massachusetts in solving our present difficulty, let us take a look at the more strictly legal aspect of the situation. Of the other states in the Union, fourteen recognize the midwife by expressly exempting her from the provision of the medical act. Most of the states ignore the situation entirely; probably in many of these the midwife plays a very unimportant rôle, if any at all.

In the few states that have attempted to license and regulate this class of practitioners, their attempts in the light of what we have seen in other parts of the world are pitifully futile. No state has successfully solved the problem. Those that have passed laws for their regulation throughout the state have, in our opinion, made the solution of the problem more difficult.

We in Massachusetts are in a most fortunate and enviable position. In the first place, the number of midwives existing is small and without influence. They are practicing in open defiance of the law. In excluding these women from practice by enforcing the law, we would not be depriving a large class from earning their livelihood. Neither would we be depriving any considerable portion of society of proper care. We are particularly fortunate in having a definition of the practice of medicine handed down by the Supreme Court of our Commonwealth, directly applying to the practice of the midwife. The following is a quotation from the opinion handed down by Mr. Justice Rugg. He writes:[27]

"Revised Laws, Chapter 76, Section 7, mentions obstetrics as one of the subjects of examination for the purpose of testing an applicant's fitness to practice medicine. This goes far towards showing that obstetrics is a branch of the practice of medicine. It requires no discussion to demonstrate that when, in addition to ordinary assistance in the normal cases of childbirth, there is the occasional use of obstetrical instruments, and a habit of prescribing for the conditions described in the printed formulas which the defendant carried, such a course of conduct constitutes the practice of medicine in one of its branches.

"Although childbirth is not a disease, but a normal function of women, yet the practice of medicine does not appertain exclusively to disease, and obstetrics, as a matter of common knowledge, has long been treated as a highly important branch of the science of medicine."

There have been at least two convictions in the state under the present law.[28] But while this shows that prosecutions are possible, it is admittedly a fact that such a process is by no means easy.

Complications in the legal machinery, not to say defects, make it difficult to bring the midwife before the bar of justice. In the first place, there is no easy method of lodging a complaint. The Board of Registration of Physicians is not empowered to discover violations of the law relating to the registration of physicians. That law distinctly states[29] that the board shall investigate all complaints of the violation of the law and report the same to the proper prosecuting officers. Thus the board does not act until a complaint is brought to them that an individual is practicing medicine without being properly licensed. Then, and not till then, it has the power to act, but persons are not anxious to go out of their way to stir up trouble unless some flagrant case arises. Should the physicians at large know that they can bring in a complaint to the Board of Registration, and yet conceal their identity, possibly more complaints would be made and more cases prosecuted.

But it is also difficult to secure sufficient data to bring about a successful prosecution. The present law for the registration of births allows so much time to elapse before the certificate must be handed in that it is often difficult to trace the case.

But more important than all is the fact that public sentiment is not sufficiently aroused to make convictions popular. In many localities officers of the law are unwilling to prosecute cases even when the law and its violations are directly brought to their attention. In one city in Massachusetts when the city marshal was informed of the law and the fact that a midwife was openly violating it, and that by a decision of the Supreme Court the midwife was liable, he replied that in his opinion the judge who would make such a decision merely gave evidence of intoxication. When such is the popular feeling, we cannot expect much result from the laws as they now exist, or in mere modification of the law. What we must first do is to arouse public sentiment, and first of all we must have the

enthusiastic support and united action of the medical fraternity.

That the situation in Massachusetts is in need of improvement, we admit most frankly. We also feel that minor changes in the present laws cannot be made too quickly, and we urge strongly that side by side with the education of the community to combat this evil should go changes in legislation which will make the laws consistent and easier of enforcement.

We feel that the most important change should be in the laws governing the registration of births. The word "midwife" as it occurs, should be at once erased from the statute books. The certificates of birth should be returned by the physician promptly; the form of the certificate could also be improved by providing a means of identification of the person actually responsible for the delivery of the patient. We also feel that theoretically better results would be obtained should the birth certificate be inspected by the board of health within three days of the birth of the child. Under the present law death certificates have to pass through this channel, and suspicious cases are referred by this board to the medical examiner. Would not inspection of birth returns by the board of health assist in furnishing evidence useful in the prosecution of questionable practitioners?

Another law which we feel could easily be amended and which would give better results is one to strengthen the Board of Registration in Medicine. This might read something as follows:

"An Amendment to the Revised Laws, Chapter 76, Section 6.

"It shall be the duty of the board furthermore to keep itself informed of the condition of the practice of medicine throughout the Commonwealth, to the end that illegal practice of medicine, as defined in this law, may be prevented. In order to secure the information required by this act there may be expended a sum not exceeding $2,000 annually."

Above all, we must make the physicians of Massachusetts thoroughly aware not only of the existing conditions of midwifery in Massachusetts, but of how they can aid by doing their duty in the enforcement of the law to the benefit of the community. In those cities and towns where the problem is greatest, the physicians should see to it that provisions are made for an out-patient, lying-in department as an accessory to the local hospital.

A brief study of such institutions in Boston would show how easily such a department can be carried out, and how easy it would be to make it practically self-supporting, and what a benefit such an institution would be to their community. The professors of obstetrics in the medical schools of Massachusetts should impress upon their students not only the importance of post-graduate work in a lying-in hospital, but also where in the state such appointments can be had. Thus by co-operation between the local practitioners in the communities where the midwife now flourishes, and the professors and students of our medical schools, not only could the present midwife situation be greatly improved, but also the medical student would have a better opportunity to obtain training in this important branch of medicine.

## CONCLUSION.

In reviewing the midwife situation abroad and in our own country, much has been said, but far more might be said of the unsatisfactory condition of obstetric practice wherever the midwife exists. Two standards of skill and a divided responsibility inevitably are found. The midwife must either be a competent, trained obstetrician, or she must become a subordinate, co-operating with the obstetrician, as does our excellent trained obstetrical nurse, relying on his judgment and resting with him the responsibility of the two lives, before a system harmonious and satisfactory can result.

The history of temporizing with the ignorant, half-trained, often malicious midwife in our sister states to-day reads like many another misguided "freedom" which is virtually a license by the state to practice quackery on an ignorant, unspecting public. The women and infants pay for this "freedom" in deaths, unnecessary invalidism and blindness.

Who are to blame? Is it the ignorant public? Shall we blame the legislators? We believe it to be the duty and privilege of the medical profession of America to safeguard the health of the people; we believe it to be the duty and privilege of the obstetricians of our country to safeguard the mother and child in the dangers of childbirth. The obstetricians are the final authority to set the standard and lead the way to safety. They alone can properly educate the medical profession, the legislators and the public.

A resolution of the Women's Municipal League awaits only a formal endorsement to urge the importance of legislation, not for the licensing and regulating of the midwife, but for such minor changes in the laws as will make the present statutes effective in dealing with the midwife in Massachusetts.

It has remained for this and other active charitable organizations to point out the necessity for bettering obstetric conditions in the state. Let the medical profession, we urge, not only co-operate with these forces for good, but let us obstetricians consider well the situation in obstetrics throughout the state to-day; let us look into the future and consider means for furnishing efficient trained service to rich and poor alike.

Our worthy predecessors of this town,[20] a century and a half ago, retired the midwife to oblivion as having passed her age of usefulness. Oliver Wendell Holmes[30] over seventy years ago, by his monograph on the "Contagiousness of Puerperal Fever," led the world to the safeguarding of the mother during childbirth.

Two recent papers, "When to Interfere in Pregnancy and Labor,"[31] and "The Fundamental Conceptions which should Govern Modern Obstetric Practice,"[32] read by two members of this society, are convincing proof that the best knowl-

edge of practical obstetrics to-day is here available, and, moreover, the lines for advance are being laid out for the future.

A golden opportunity awaits the obstetricians of Massachusetts to-day to carry on this high standard. Our already fairly satisfactory system should be maintained and advanced along the lines of the most progressive sociologic, economic and obstetric knowledge of the day.

Thus Massachusetts may be kept in her position of leader, guide and example of the best, safest and most efficient system of obstetric practice in this country and throughout the world.

## SOME PRACTICAL POINTS IN CONNECTION WITH DISLOCATION OF THE HIP, AND ITS REDUCTION BY THE METHOD OF BIGELOW.

BY GEORGE H. MONKS, M.D., BOSTON.

IT has often occurred to me that the subject of dislocation of the hip, as it is treated in textbooks, has been made so complicated that the student who tries to understand it, and even the practitioner who wishes to refresh his memory, can hardly grasp the essential points in such a manner as to be much use to him in practical work. It is for the purpose of presenting a simple clinical classification, and also an easy method for remembering the steps in reduction (the Bigelow method is the one here especially referred to), that this paper is written.

For many years I have been in the habit of demonstrating on the cadaver, before the classes in surgery at the Harvard Medical School, the different dislocations of the hip, and also the methods of reduction. The experience acquired in this way, and also in connection with a number of cases which I have seen and treated, has convinced me that, for practical purposes at least, dislocations of the hip (so long as the Y ligament is unruptured) may roughly be divided into *two classes:*

1. Those dislocations in which the head of the femur lies behind the acetabulum.

2. Those dislocations in which the head of the femur lies in front of the acetabulum.

Any dislocation belonging to the first class is called a *posterior* dislocation; and any dislocation belonging to the second class is called an *anterior* dislocation.[1]

In each class there are several varieties according to the exact position of the head of the bone. For practical purposes, however, it is seldom necessary to consider a dislocation more in detail than to note that it belongs either to the class of posterior dislocations or to that of anterior ones.

The *posterior dislocation* is comparatively common; almost all the dislocations which one sees or hears of are of this variety. The appearance of such a dislocation is very characteristic. The affected limb is strongly inverted, and its slightly flexed knee is carried across the other knee. The limb is rigid, the thigh is somewhat flexed at the hip, and the rounded head of the femur can be felt on the dorsum ilii.

The *anterior dislocation*, in any of its forms, is extremely rare. Many a surgeon of large experience has never seen a case of it. The whole limb is more or less everted, and efforts to invert it meet with resistance which cannot be overcome. The leg is away from the median line of the body, and the internal condyle of the femur (which, as Bigelow pointed out, always looks in the same direction as the head of the bone) exhibits a tendency (always present, but more pronounced in some cases than in others) to face forwards. In well-marked cases the head of the bone may be felt just below Poupart's ligament.

It is generally agreed that almost all dislocations of the head of the femur, when the Y ligament is not ruptured, begin in the same way: that is to say, the head of the bone breaks through the lower part of the capsule and then goes backwards or forwards according to the character and direction of the forces applied to it.

Usually the *diagnosis* of dislocation of the hip is easy enough. Occasionally, however, there are cases in which the real condition is not entirely clear. Under such circumstances a skiagraph, including both hips, may remove the doubt. An examination under ether, when the muscles are relaxed, may also be of assistance.

For the *reduction* of a hip dislocation the patient is placed upon a blanket spread on the floor and a pillow is put under his head. He is then etherized until his muscles are thoroughly relaxed.

[1] Allis, in his classical work on the hip (the Samuel D. Gross Prize Essay, 1895), expresses his conviction "that all conceivable dislocations are primarily either inward or outward, and that from these primary positions the head may be secondarily shifted to any point above the socket within the reach of the remnant of untorn capsule that binds the shaft to the rim above the socket."

I have used the words "anterior" and "posterior" as being, in my opinion, preferable from a clinical point of view. Certain possible dislocations, such, for instance, as those classed by Allis under the headings "reversed thyroid" and "reversed dorsal," would probably find no proper place in the classification I have suggested; but such dislocations must in practice be so extremely rare that they can be neglected.

The surgeon, realizing that the displaced head of the bone must be made to return to the socket by the same route which it made for itself on leaving it, decides how he will manipulate the leg in order to bring about this result. He stands on the patient's left side,[2] with his left foot advanced close to the patient's pelvis, and, while an assistant holds the pelvis firmly to the floor, he firmly grasps the lower leg (his right hand being around the leg just above the ankle and his left one supporting the leg just below the tuberosities of the tibia) and flexes the lower leg at the knee and the thigh at the hip. In the process of doing this, however, he should make the patient's knee describe a horizontal curve, which is either *inward or outward* according to the dislocation. At the end of this maneuver the head of the bone is presumably just beneath the torn part of the capsule, and, therefore, the surgeon then forcibly *lifts* the thigh directly upwards,[3] when the head of the bone usually slips into its socket. A folded towel should now be placed between the two inner malleoli, and the ankles bandaged loosely together.

The point in all this which seems to be most difficult to remember is whether the surgeon, when he flexes the thigh upon the pelvis, should make the knee describe an *inward* or an *outward* curve. It is one of the objects of this paper to suggest a simple rule for remembering this point.

If, as the patient lies etherized on the floor before him, whether the dislocation is posterior or anterior, the surgeon will imagine that there is, on the exposed side of the patient's lower leg, an arrow *pointing towards the knee* (when that knee is flexed), this arrow will indicate the direction in which he is to carry the knee while he is flexing the thigh upon the pelvis. By consulting Fig. 1, which shows a posterior dislocation, he will see that during flexion the knee should be made to describe an inward curve (internal circumduction of the femur). On the other hand, by consulting Fig. 2, representing an anterior dislocation, he will see that during flexion the knee should be made to describe an outward curve (external circumduction of the femur).[4]

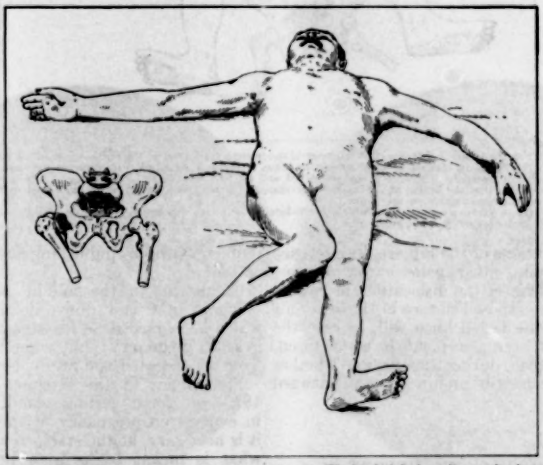

FIG. 1. Posterior dislocation of the head of the femur. The head of the bone lies on the dorsum ilii, and, as the Y ligament is unruptured, the thigh is strongly inverted. The knee is flexed and the foot rests upon its inner border. The arrow indicates that flexion at the hip-joint preliminary to reduction should be accomplished by internal circumduction of the femur.
[Drawn from a cadaver upon which this posterior dislocation had previously been produced.]

## CONCLUSION.

The points which in this paper I wish especially to emphasize are (1) that, for practical purposes,

[2] If the left femur has been dislocated, the surgeon stands between the patient's legs.

[3] It is oftentimes better at this stage for the surgeon to slip his left forearm under the upper part of the patient's lower leg so as to get more power in lifting.

[4] Some surgeons claim that during this excursion of the head of the bone the sciatic nerve or some other structure may be caught, and, therefore, they prefer Allis's method of reduction. My reason for employing the Bigelow method is that I am more used to it than I am to that of Allis, and also because personally I have only once found much difficulty (although, of course I may at any time meet with it) in reducing dislocations by Bigelow's technic. Allis's method, which may be used instead of Bigelow's, or in the event that the Bigelow fails, is, as I understand it, as follows:

*For posterior dislocations:*

(1) Flex thigh to a right angle.
(2) Turn lower leg outwards until it is at right angles with the body (keeping thigh vertical). This is done for the purpose of freeing the sciatic nerve or any tendons that may be caught over the head of the bone.
(3) Lift up thigh vertically (in order to bring head opposite acetabulum).
(4) Turn lower leg inwards until it is again in the axis of the body. During this process the lifting should be continued.
(5) Extend thigh.

*For anterior dislocations.*

(1) Flex thigh to a right angle and make traction in axis of femur.
(2) Assistant pushes head of bone into acetabulum.
(3) Adduct thigh.
(4) Extend thigh.

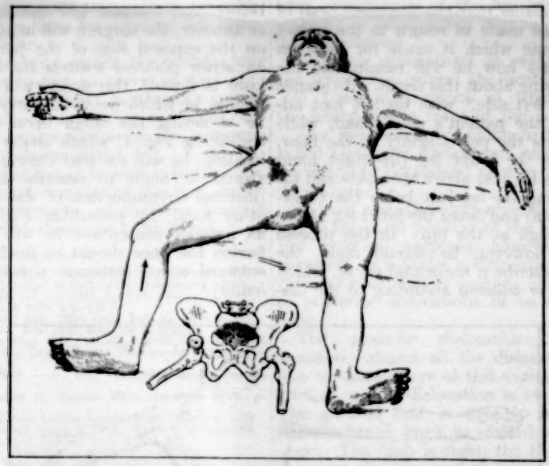

FIG. 2. Anterior dislocation of the head of the femur. The head of the bone is just below Poupart's ligament, making a visible projection there. As the Y ligament is unruptured the thigh is strongly everted. The knee is slightly flexed and the foot rests on its outer border. The arrow indicates that the flexion at the hip-joint preliminary to reduction should be accomplished by external circumduction of the femur.
[Drawn from a cadaver upon which this dislocation — a very extreme type of anterior dislocation — had previously been produced.]

all regular dislocations of the hip are, in reference to the acetabulum, either *posterior* or *anterior;* and (2) that, whichever the dislocation, an imaginary arrow on the exposed surface of the lower leg pointed toward the flexed knee will, in case the Bigelow method of replacement is to be used, remind the surgeon during the flexion whether to make the knee describe an inward or an outward curve.

## OVARIAN PREGNANCY. REPORT OF A CASE.

BY ERNEST BOTEN YOUNG, M.D.,
*First Assistant Visiting Physician for Diseases of Women, Boston City Hospital; Instructor in Gynecology, Harvard Medical School;*
AND
LAWRENCE J. RHEA, M.D.,
*Instructor in Pathology, Harvard Medical School; Pathologist to the Children's Hospital, Boston; Assistant Pathologist, Boston City Hospital.*

THE Arabian physician, Albucasis, of the eleventh century after Christ, is said to have first described extra-uterine pregnancy, but it was not until at the beginning and end of the seventeenth century that ovarian pregnancy was mentioned by Mercerus and St. Maurice, in 1614 and 1682 respectively.

Velpeau, in 1835, and Mayer, in 1845, expressed the opinion that none of the previously reported cases could be considered as undoubtedly in the ovary; while Lawson Tait, and Bland-Sutton, until recently, held that every ovarian pregnancy had its beginning in the Fallopian tube.

The possibility of ovarian gestation, although denied by English authors until the last few years, has been admitted by most German writers, Kiwisch publishing such a case as early as 1851.

Cohnstein, in the middle of the nineteenth century, first laid down definite requirements, which he regarded as necessary for the proof of ovarian pregnancy; but some of his postulates were not accepted and are evidently inadequate.

Spiegelberg in the *Archives für Gynäkologie*, 1878, set forth certain conditions as essential in every true pregnancy of this type, and since it is necessary, at the start, to clearly understand what is meant by ovarian pregnancy, his requirements are repeated, as they have been generally accepted:

I. An intact tube on the affected side.

II. A fetal sac occupying the position of the ovary.

III. Connection of the sac with the uterus by the ovarian ligament.

IV. A sac wall containing ovarian tissue.

Jacobson adds two additional requirements to those of Spiegelberg, viz.:

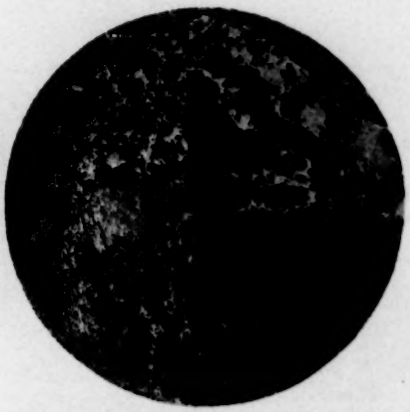
(*a*) The fetus visible in a cavity of the ovary.

(*b*) Demonstrable organic connection between fetus and ovary.

Williams has also pointed out that ovarian tissue should be found in "several portions of the sac wall at some distance," as the ovary may be flattened through the pressure exerted by a pregnancy in the broad ligament or tube and apparently form a part of the covering of the fetus, although such would not be in reality the fact.

It is also to be remembered that ovarian tissue, changed by pressure and infiltration, may lose its characteristic structure.

Werth considers the conditions imposed by Spiegelberg too exacting, and allows all cases, with such anatomical relations as demonstrate connection with the ovary and dissociation with uterus and Fallopian tubes (either accessory or the fimbria ovarica), to stand as true examples of this anomaly. However, this question is not yet settled, for opinions still differ as to the acceptance of certain reported cases. Williams and Norris disagree in no less than four instances.



The frequency of this form of extra-uterine follicle; (2) to enter through a rupture which afterward closes; (3) to enter a follicle into which an unruptured follicle subsequently discharges its ovum. There is said to be no definite decidua formation in the process of implantation, the villi forcing their way into the blood vessels, as in uterine gestation.

The theory of Webster, that Müllerian tissue must be present for the implantation and development of the impregnated ovum, is not generally accepted.

OVARIAN PREGNANCY — YOUNG

SECTION 1. Showing normal lumen of tube.

SECTION 1. Another field. Showing cyst wall with chorionic villi immediately beneath the tube.

(including 44 extra-uterine pregnancies, 58 hemorrhagic cysts of the ovary and 62 small ovarian tumors) only 1 ovarian pregnancy came to light.

Of a large number of such specimens from the Gynecological Service at the Boston City Hospital, and examined in the Pathological Laboratory, not one has shown any evidence of pregnancy.

It is hardly necessary to say that the earlier the stage of pregnancy, the more certain the diagnosis.

The theories as to the manner of occurrence are pure conjecture. The spermatozoon is supposed: (1) to enter the unruptured Graafian

each side, and an enlarged left ovary. The appendages and uterus were quite movable and the old inflammatory process seemed quiescent. No special tenderness on examination.

A few days later I saw her at a private hospital, and found the mass on the left side of the pelvis much increased in size and quite symmetrical, but the exact limits ill-defined. The ovary on the right was enlarged.

Ectopic pregnancy was considered in the case; but as the physician, who had known her for some time, did not think this probable, and the patient denied any such possibility, a cyst was considered as a possible diagnosis.

The following day the abdomen was opened and a small amount of black fluid blood was found at the

was not until at the beginning and end of the seventeenth century that ovarian pregnancy was mentioned by Mercerus and St. Maurice, in 1614 and 1682 respectively.

Velpeau, in 1835, and Mayer, in 1845, expressed the opinion that none of the previously reported cases could be considered as undoubtedly in the ovary; while Lawson Tait, and Bland-Sutton, until recently, held that every ovarian pregnancy had its beginning in the Fallopian tube.

(*b*) Demonstrable organic connection between fetus and ovary.

Williams has also pointed out that ovarian tissue should be found in "several portions of the sac wall at some distance," as the ovary may be flattened through the pressure exerted by a pregnancy in the broad ligament or tube and apparently form a part of the covering of the fetus, although such would not be in reality the fact.

It is also to be remembered that ovarian tissue, changed by pressure and infiltration, may lose its characteristic structure. .

Werth considers the conditions imposed by Spiegelberg too exacting, and allows all cases, with such anatomical relations as demonstrate connection with the ovary and dissociation with uterus and Fallopian tubes (either accessory or the fimbria ovarica), to stand as true examples of this anomaly. However, this question is not yet settled, for opinions still differ as to the acceptance of certain reported cases. Williams and Norris disagree in no less than four instances.

The frequency of this form of extra-uterine pregnancy is given in a recent textbook on obstetrics as 4.8%, and if all reported cases are accepted, such may be correct; but if the proofs required by Spiegelberg and Jacobson are strictly followed, the percentage is far too great, for earlier writers included simple dermoid cysts in their series, and there are many questionable cases in medical literature, within sufficient data, both anatomical and microscopical.

Williams found only 3 cases published in England during the nineteenth century: 2 by Granville in 1834 and 1 by Oliver in 1896. In the United States, Thompson, in 1892, published the first indubitable case, since which Webster, in 1904 and 1907, Norris and Mitchell, and Jacobson, in 1908, Morris, in 1909, have presented well-proven examples.

Williams, after a careful study of the literature on this subject up to 1906, classified only 13 cases as "positive," all of which were carefully described and studied with the microscope. Two of these reached full term; one became a lithopedion and was retained thirty years; the other was associated with an intra-uterine pregnancy which terminated normally. In the last case, several days after the delivery of the uterine child, Ludwig removed, by laparotomy, the living extra-uterine child and also the gestation sac. The other 11 cases all ended before the fourth month. In 4 cases the fetus was still within the ovary.

Norris and Mitchell report, using the classification of Williams, 16 "positive," 15 "possible," and 9 "fairly probable" cases. Since their article, I have been able to find but 3 authenticated cases, those of Jacobson, Norris and Kerr.

The question might naturally arise as to whether this form of ectopic pregnancy would not be discovered more often if the blood cysts of the ovary were examined; but Norris and Mitchell report that in the study of 1,700 gynecological specimens at the University of Pennsylvania (including 44 extra-uterine pregnancies, 58 hemorrhagic cysts of the ovary and 62 small ovarian tumors) only 1 ovarian pregnancy came to light.

Of a large number of such specimens from the Gynecological Service at the Boston City Hospital, and examined in the Pathological Laboratory, not one has shown any evidence of pregnancy.

It is hardly necessary to say that the earlier the stage of pregnancy, the more certain the diagnosis.

The theories as to the manner of occurrence are pure conjecture. The spermatosoon is supposed: (1) to enter the unruptured Graafian follicle; (2) to enter through a rupture which afterward closes; (3) to enter a follicle into which an unruptured follicle subsequently discharges its ovum. There is said to be no definite decidua formation in the process of implantation, the villi forcing their way into the blood vessels, as in uterine gestation.

The theory of Webster, that Müllerian tissue must be present for the implantation and development of the impregnated ovum, is not generally accepted.

Norris has pointed out, that since nearly one half of the doubtful cases have gone the full term, the ovary accommodates itself to the enlargement of pregnancy more readily than the Fallopian tubes. The present writer would also suggest that this is borne out by the extreme distention undergone in the formation of the large ovarian cysts, although in pregnancy, the changes at the site of the developing placenta, unless favorably implanted, might so weaken the wall as to often cause rupture before adequate distention could take place. In symptomatology, ovarian pregnancy resembles other forms of ectopic gestation, and hence nothing further need be said on this subject.

### REPORT OF CASE.

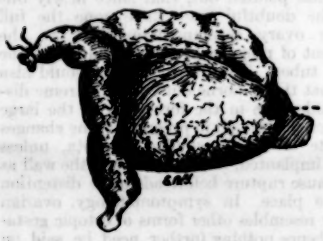
Z. F., twenty-seven years of age, single, was referred to me by her physician in October, 1908, as a probable case of fibroids of the uterus.

*Previous history.* — Rheumatic fever in 1904, and measles and diphtheria in 1908. Catamenia regular and painless before beginning of present disturbance, with moderate flow for five days. Pain in lower abdomen about one year before irregular flowing began, but no painful micturition or subjective symptoms of acute infection.

*Present illness.* — In February, 1908, had excessive catamenial flow and was curetted by the physician in the town where she was living at the time. Flowing continued at irregular intervals until about ten days before I saw her, but moderate in amount. During these ten days there were three attacks of profuse flow and a slight bloody discharge between times.

*Physical examination.* — Well-developed, rather spare woman. Color fair. Temperature, 98.6°. Heart apex in nipple line; impulse slightly irregular, but of good strength. Systolic murmur at apex; not transmitted. Pulse 80, of fair strength and volume, but slightly irregular. Palpation of abdomen negative. No objective signs of pregnancy.

*Vaginal examination.* — Hymen broken. A slight bloody discharge from the uterus. Uterus 3° retroversion, with tubes somewhat adherent to pelvis on each side, and an enlarged left ovary. The appendages and uterus were quite movable and the old inflammatory process seemed quiescent. No special tenderness on examination.



A few days later I saw her at a private hospital, and found the mass on the left side of the pelvis much increased in size and quite symmetrical, but the exact limits ill-defined. The ovary on the right was enlarged.

Ectopic pregnancy was considered in the case; but as the physician, who had known her for some time, did not think this probable, and the patient denied any such possibility, a cyst was considered as a possible diagnosis.

The following day the abdomen was opened and a small amount of black fluid blood was found at the

brim of the pelvis, and abundant evidence of an old pelvic peritonitis. On separating a few recent adhesions, there appeared a large, recent blood clot in the left side of the pelvis, completely surrounding the ovary, which contained what appeared to be a large corpus hemorrhagicum.

The ovary was nowhere adherent to the bowel, and its connection with the uterus and broad ligament appeared normal. The fimbriated end of the tube, on this side, was closed and adherent in the bottom of the pelvis; the remaining portion free, except for a few old, long and light adhesions to the bowel.

Before section.

The sac in the ovary, containing old, black blood clot, was slightly ruptured at its outer end, as shown in the drawing, and from this the blood exuded.

The right ovary was polycystic and contained no corpus hemorrhagicum; but as the ostium of the right tube was injured in the process of removal, its exact condition cannot be stated. It was apparently partially open, but quite firmly adherent to other structures.

A few days later the specimen, which had been placed in formalin, was cut in the presence of Dr. H. C. Low, pathologist to the Children's Hospital, and we both saw the small embryo lying in the rounded space, almost exactly as figured in the article by Jacobson, in the Twenty-fifth Anniversary Publication of the New York Post-Graduate Medical School and Hospital, 1908.

The drawings of the specimen, closed and sectioned, were made immediately and show the exact conditions, except that, by the action of the formalin, the connection between ovary and tube seems more intimate than was actually the fact.

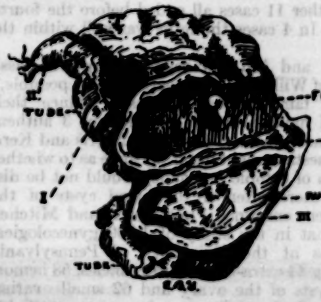
Clinically, this case appears one of true ovarian pregnancy, as an embryo was found in the blood clot contained in tissue corresponding to a part of the ovary, the ovary itself being surrounded by blood clot and connected to no other structure except in the normal manner. The ostium of the tube on the same side was closed; and opposite tube showed no disturbance except such as may come from pelvic peritonitis. The blood clot was entirely about the left ovary and did not reach the tube on the right. The right ovary showed no corpus hemorrhagicum.

The pathological report by Dr. Rhea gives further particulars in regard to the specimen.

PATHOLOGICAL REPORT. (DR. RHEA.)

The gross specimen was delivered to me after it had been in 10% formalin for some time and had already been opened as referred to in Dr. Young's description.

The gross specimen consists of a thin-walled cyst 3 by 2 cm. which had been opened. Loosely adherent to this cyst, but easily separated from it, is the Fallopian tube, which had been cut across near its central portion. The wall of the cyst varies from 3 mm. to 1 cm. in thickness; it is lined by friable blood clot. The fimbriated extremity of the Fallopian tube is occluded. The tube is somewhat tortuous; its lumen is patent and slightly larger than normal; it is free from blood clot. Several sections were taken from the specimen for microscopical examination; the areas examined are indicated upon the drawing of the gross specimen.



*Section I.* — Central portion of Fallopian tube. A transverse section of the Fallopian tube and adherent cyst wall at this point shows no evidence of tubal pregnancy; the lumen of the tube is patent; its muscular coats are slightly infiltrated by lymphocytes. There are no villi or decidual cells in the coats of the tube. The wall of the adherent cyst described above contains chorionic villi and a large amount of red blood corpuscles. The products of conception do not extend into or involve the muscular coats of the Fallopian tube itself.

*Section II.* — Fallopian tube, proximal region. The lumen is patent and free from blood clot. The muscular coats are infiltrated with small lymphocytes. There are no chorionic villi or decidual cells anywhere in the section.

*Section III.* — Cyst wall. The cyst wall contains smooth muscle of the ovary, dilated blood vessels, a few blood corpuscles in the tissue and an occasional chorionic villus. The wall of the cyst is lined with lamellated blood clot.

*Section IV.* — Cyst wall. The cyst wall is infiltrated with red blood corpuscles. There are no chorionic villi. The cyst is lined with lamellated blood clot.

The gross and microscopical study show, in brief, the following: A Fallopian tube free from blood clot and without evidence of pregnancy having taken place in it. The cyst wall contains recent hemorrhage, and sections I and III show chorionic villi. In Section III the chorionic villi are in tissue that is evidently ovarian. Micro-photographs of Section I are reproduced.

After section. Numerals show site of sections examined.

A very complete bibliography of this subject will be found with the three articles, references to which are given below.

## Clinical Department.

### A NOTE ON THE SYMPTOMATOLOGY OF ABSCESS OF THE LIVER.

BY WILLIAM C. QUINBY, M.D., BOSTON.

ALTHOUGH it is well known that the symptoms caused by liver abscess are frequently vague and perplexing, the clinical picture presented by the following case is sufficiently unusual to make it worthy of record.

A traveling salesman, forty-six years old and married, presented himself for treatment on the 7th of November, 1909, complaining of pain in the epigastrium. Though a resident of Boston, his occupation called him on long active trips through the Middle West, two such being made each year. Before this illness he has needed medical advice on but two occasions since childhood; once three years ago for a pleurisy on the right side from which he recovered entirely in three weeks, and again a year ago for a slight infection of the left hand. His habits had always been good, and he denied having had any venereal disease. He has had no dysentery.

The present illness began during full health, seven weeks before these notes were made, as a severe sharp pain in his "stomach" after a dinner of chicken. This continued through that night and the next morning. There was no vomiting or diarrhea, though he was chilly and thinks that he had some fever. In spite of the fact that he was quite sore to the touch in the stomach region after this, he continued to work for the next three weeks. Though digestion had been normal before this attack, any solid food taken since has caused pain and soreness. Eructations of large amounts of gas also made their appearance. There had never been jaundice, hematemesis or melena. The pain increases markedly on deep inspiration or on stooping to tie the shoes. It has always been localised sharply to an area just below the ensiform. Since the first attack seven weeks ago he has lost twenty-five or thirty pounds in weight, and notices also a marked diminution in strength. The past four weeks have been spent at home loafing about the house, often on the bed and using a linseed poultice. He does not think that there has been any fever since the original attack. The bowels have moved normally and nothing unusual has been noted in regard to the stools. There are no urinary symptoms.

Examination showed a well-developed man, rather poorly nourished, of sallow complexion, looking at least ten years older than the given age. The skin and mucous membranes are not jaundiced. The tongue is coated, the teeth rather poor. The thoracic organs are normal, though breathing seems rather shallow. Volume and tension of the pulse are good; its rate, 72 per minute. Litten's sign is present on each side. The liver dullness extends from the sixth rib to costal margin in the mamillary line. High in the epigastrium is a tumor, smooth and not adherent to the skin, filling the whole region and extending about 10 cm. downward from the ensiform. It is dull on percussion, the dullness being continuous with that of the heart on the left and of the liver on the right. At its right and left limits the tumor is somewhat tender on pressure. The feeling conveyed is that of tense, deep fluctuation. There is no mobility of the tumor, except that on deep inspiration it seems to move downward slightly with the diaphragm. Neither visible peristalsis nor muscular spasm is present. The rest of the abdominal examination is normal. There are no piles, and the genitalia and extremities are without note. The temperature is normal. Examination of urine, blood and feces failed to show anything of note. Inflation of stomach and colon did not alter in any way the dullness outlines of the tumor. The Wasserman reaction was negative.

On the 10th of November, 1909, operation revealed a large abscess of the left lobe of the liver, containing about a pint of necrotic, purplish-red material interspersed with flakes and particles of a distinctly purulent aspect. At a spot on the upper surface of this lobe the abscess wall was thin and united to the parietal peritoneum by recent adhesions. No evidence of further disease of the liver could be made out. Its right lobe was of normal size, its lower border coming just to the edge of the ribs. The rest of the abdominal organs were normal so far as could be determined. The cavity was drained by a large tube held in place by a couple of stitches.

Examination of the abscess material showed it to be sterile, with no evidence of echinococcus. After a rapid convalescence of three weeks the cavity had so filled in and shrunken together that the patient could leave the hospital with but a small granulating skin area.

One year later, though he still appears somewhat sallow, his only complaint is that he tires easily. He has been actively engaged at work and has regained the weight previously lost, but has not gone above it.

Here is presented a case of single abscess occurring in the left lobe of the liver of which the only primary symptom was very rapid loss of weight and strength. To this was added pain, when the thinning of the abscess wall caused the peritoneum to become involved. The discomfort following food, deep breathing and stooping over is explained in a purely mechanical way through the presence of this adhesion. Etiological factors such as residence in the tropics or suppurative focus elsewhere in the body were entirely absent. That the abscess had existed for a considerable period before the patient became aware of it is probable both on account of its size and the sterile nature of its contents, but that it could have been present for a year as a sequel of the infection of the hand seems hardly credible. Its pyogenic nature seems established beyond a doubt because of the freedom from any further symptoms during the past year. This would hardly have been the case had a necrotic gumma or a neoplasm been the underlying cause.

### THE DISAPPEARANCE OF A CATHETER IN THE BLADDER AND ITS SUBSEQUENT SPONTANEOUS PASSAGE.

BY W. B. WILSON, M.D., PAWTUCKET, R. I.,

*Attending Surgeon to St. Joseph's Hospital, Providence, R. I., and the Memorial Hospital, Pawtucket, R. I.*

DURING the second week of an attack of typhoid fever from which a young man twenty-eight years of age was suffering, he had difficulty in passing water, so much so that his physician was compelled to catheterise him and had to repeat the operation several times. The last time he catheterized him he emptied the basin before withdrawing the instrument, which was of a soft rubber type, No. 10 English. On returning to withdraw the catheter he was astounded to find that it had disappeared. He made several attempts to grasp it, but all were ineffectual. I was called with the

idea of immediate removal, but it struck me after I had satisfied myself that the catheter was wholly in the bladder, that, being probably sterile and the patient being pretty sick, not much harm would follow leaving it there and that the traumatism attendant upon removal might be the turning point in the critical stage of a dangerous disease. I, therefore, counselled washing out the bladder daily with sterile water. On the seventh day after the accident, after the physician had washed out the bladder, that organ being partially filled, the patient had a desire to strain and out came the catheter, eye-end first. There was no cystitis nor any other untoward result. The patient made a complete recovery from the typhoid.

As I never heard before of a catheter being passed spontaneously, I thought it might be worth reporting.

## Reports of Societies.

### SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

TWENTY-THIRD ANNUAL SESSION, HELD AT NASHVILLE, TENN., DEC. 13, 14 AND 15, 1910.

THE President, DR. W. O. ROBERTS, Louisville, Ky., in the chair.

#### THE IMPORTANCE OF PRESERVING THE GALL BLADDER.

DR. J. W. LONG, of Greensboro, N. C., stated that a critical analysis of 86 of his own operative cases had convinced him of the value of retaining the gall bladder. Cholecystectomy should be done in the presence of new growths, especially primary carcinoma; also in gangrene when the whole thickness of the bladder wall was involved, but not otherwise, since he had had several recoveries following drainage for gangrenous mucosa of the bladder. Infection and empyema were only relative indications for doing cholecystectomy, most cases doing well under cholecystotomy. The cystic duct obstruction always present in empyema was gradually overcome under the beneficent influence of drainage, and after a varying interval of one to seven days, in one instance fifteen days, bile began to discharge through the duct. Stone impacted in the cystic duct was only a rare indication for cholecystectomy, the writer never having failed to remove the stone. Even perforation could not be considered an absolute indication for cholecystectomy, the writer reporting two cases which did perfectly well under drainage. Drainage was second in importance only to removal of stones. Removal of stones could not cure a pancreatitis, but drainage did. No organ in the body once badly damaged responded so effectually to drainage as did the gall bladder. Drainage was the *sine qua non* for curing the patient of the widespread sequelæ of gall-bladder infection. It was prudent in doing a cholecystectomy to leave a forceps rather than a ligature on the cystic duct in order to provide for a free flow of bile should untoward symptoms arise. Embryologically, the bud for the gall bladder and that for the larger portion of the pancreas developed together; as they grew and receded from each other their ducts remained joined. The relation of the two organs was very close anatomically and physiologically. The gall bladder was not a storage pouch for bile, but rather was an expansion tank for the bile duct system. Its removal was always followed by dilatation of the ducts, even the nub of the cystic duct compensating for the loss of their expansion tank. Pure bile injected into Wirsung's duct caused pancreatitis; bile mixed with the bladder mucosa did not, — a cogent reason for preserving this function. The only avenue through which to treat chronic pancreatitis present or in the future was the bile duct system, preferably through the gall bladder.

#### DISCUSSION.

DR. THOMAS S. CULLEN, of Baltimore, stated they had for several years made it a practice to drain all gall bladders, except in those cases in which there was a suspicion of malignant disease, or where there was empyema of such a character that it was impossible to drain satisfactorily, where the danger of removing the gall bladder was not as great as that of infection from drainage.

DR. HOWARD A. KELLY, of Baltimore, stated under no circumstances would he remove a gall bladder that was apparently sound or even moderately diseased which evidently might easily recover with drainage. Again, he would not remove a gall bladder where there was any suspicion of trouble in the common duct or any pancreatic disease. It was best to remove a gangrenous gall bladder or one that was suspected to be malignant.

DR. J. GARLAND SHERRILL, of Louisville, said there had been a tendency to do too radical operations in this region. He had saved a number of gall bladders that were full of pus by drainage. The reparative power of the tissues was very great and the opening became patent in a short time, and drainage of bile free.

DR. RANDOLPH WINSLOW, of Baltimore, stated he had operated on a case some time ago where the duct was evidently obstructed; although bile reappeared, it did not flow. However, in the course of time nothing but mucus came from the external opening; the gall bladder was distended, and bile did not pass. There occurred stricture of the cystic duct which necessitated a second operation for the removal of the gall bladder.

DR. R. E. FORT, of Nashville, said in those cases where they had a small contracted, rigid, friable gall bladder, not larger than the finger, in which drainage could not be instituted, he thought it not only proper but essential to do a cholecystectomy. There were cases occasionally in which they had common duct obstruction and it became necessary to do cholecystectomy, but in other cases it was not necessary to do this radical operation.

DR. BACON SAUNDERS, of Fort Worth, Tex., stated in these old chronic gall bladders it was necessary to continue drainage sometimes for six weeks in order to get satisfactory results.

DR. WILLIAM B. COLEY, of New York City, said when he removed a gall bladder he instituted drainage in the cystic duct and this did as much good to the pancreas as if they drained through the gall bladder itself.

DR. LONG, in closing, stated in gall-bladder surgery, as in all other surgery, it was largely a matter of personal equation in deciding what was the best thing to do in the individual case.

#### CHRONIC URETHRITIS AND CHRONIC URETERITIS CAUSED BY TONSILLITIS.

DR. GUY L. HUNNER, of Baltimore, in a paper on this subject contended that certain cases of chronic urethritis and chronic ureteritis heretofore of obscure origin were due to tonsillitis. He recognized that the great majority of chronic urethritis cases were due to gonorrhea, most of the cases of rheumatic urethritis of the older textbooks being of this nature. Some cases could be traced to trauma and infection in childhood, or trauma and infection of non-gonorrheal character in the newly married. Other cases might probably be

due to onanism, and some might be classed as auto-infections, the short female urethra and the myriads of micro-organisms normally present in the outer orifices being factors that would make auto-infection probable.

After ruling out gonorrhea and these rarer causes of infection, there still remained a certain large percentage of chronic urethritis cases, which, in recent years, he had associated with the rheumatic diathesis. He asserted that in a large proportion of this class of cases the disease was due to infections or toxins from the tonsils, and the importance of this observation was appreciated only when we recognized that the urethritis could not be permanently cured until the tonsils were thoroughly extirpated. To substantiate his views, four cases who had had the tonsil operation were reviewed in detail, and several others not operated were cited briefly. Of the four operative cases, two had been treated for months without appreciable permanent benefit to the urethra, whereas after removal of the tonsils, Case 1 recovered. The recovery was prompt, and patient had been well for fourteen months, after having had bladder trouble eight years. Case 2, after removal of the tonsils, had an irritable spot in the base of the right fauces, which for seven months gave periods of sore throat accompanied by rheumatic symptoms in the knees and urethritis symptoms. For the past four months the throat symptoms had been absent, and the joints and urethra were apparently well. Case 3 had been treated in the hospital on two occasions in the past nine years, with prompt recovery from the urethral symptoms each time. On the last hospital visit, in March, 1910, the tonsils were clipped with the tonsillotome, and the patient reported a return of all her symptoms soon after going home. Case 4 had a tonsillectomy after two urethral treatments, so no conclusions could be drawn in her case as to the futility of urethral treatments, without removal of the tonsils. She had apparently recovered after having had bladder trouble three years, although only four months had elapsed since the tonsillectomy. The various possible causes of ureteral stricture were discussed and two cases were reported to illustrate the possible causal relationship of tonsillitis. The fact that acute prostatic abscess sometimes followed inflammation of the tonsils suggested a possible relationship between the tonsils and certain chronic urethritis cases in males. These cases were often associated with chronic prostatitis, in which gonorrhea could be excluded as the cause, and for which no definite etiology had heretofore been obtainable.

DISCUSSION.

Dr. J. M. Mason, of Birmingham, said it seemed that all of the cases reported had occurred in unmarried women in whom there was some possibility of nervous disturbance or reflex irritation of the urethra. He would like to ask Dr. Hunner whether he had had any cases in married women or in women whose sexual relations were normal.

Dr. G. R. Holden, of Jacksonville, Fla., asked whether the discharge in these cases contained pus cells as seen by the microscope.

Dr. Howard A. Kelly, of Baltimore, stated the wife of a professional colleague had been under his care for fifteen years. She had more or less malaise. Careful examination revealed pus in the urine in varying amounts, but so far as the local conditions were concerned the patient was without symptoms. She was in ill-health. He catheterised and found pus came from the left kidney. He dilated the ureter on that side, washed out the kidney, she got better, and after a few months returned for further investigation and treatment. She had for twelve years been troubled with rheumatism. She had enlargement of the joints. Last spring, on examining her, he found a large, tender kidney with a good deal of pus in the urine. He drained this kidney and did a plastic on the semilunar ureteral valves. He cut down on the fascia at the end of the ureter and drained from the side. She continued to suffer with rheumatism through the summer, although she experienced some relief from the drainage in the side. This fall he took out the kidney and her rheumatism disappeared like magic.

Dr. John F. Oechsner, of New Orleans, said it seemed from the cases cited, without going into any other possible local infection, that the tonsils were at fault. He feared, however, that what had been said might lead to more or less universal tonsillectomy if the members of this representative body should regard the tonsils as always at fault in cases of urethritis, where the specific organism, the gonococcus more particularly, could not be determined. He would, therefore, make a plea to educate the practitioner to be more specific in determining the nature of a local infection, whatever it may be, and find out exactly where the focus of infection was.

Dr. Hunner, in closing, stated some of the cases he had had since the four he had reported were married women. These cases did not have pus in the urine. He stated they could not milk pus out of the urethra as they could in an acute gonorrheal case.

THE BEST METHOD OF EXPOSING THE BLADDER FOR AGGRESSIVE OPERATIONS BY THE SUPRAPUBIC ROUTE.

Dr. Howard A. Kelly, of Baltimore, pointed out the disadvantages of the method in common use, namely, of making a vertical midline incision between the recti muscles, when the muscles with their underlying fascia resisted retraction and so offered only a slit through which the bladder could with difficulty be exposed. Dr. Kelly used a transverse crescentic incision above the pubis through skin, fascia out to and even beyond the semilunar line on each side. He then separated the fascia from the muscles after the manner proposed by Pfannenstiel for operations upon abdominal and pelvic tumors. In bladder cases, however, the abdominal cavity was not opened. The recti muscles freed from their overlying fascia were flaccid and easily drawn apart, thus affording a very broad exposure of Retzius' space. The bladder was clearly brought into view by inflation with air pumped in through the urethra and was widely incised in its transverse axis, thus affording a maximum exposure of the viscus. With the bladder thus conveniently opened, all parts of the organ were perfectly exposed to view and made easily accessible to operation. The whole question of dealing with extensive ulcers, papillomata, malignant disease and cystitis requiring resection was by this means greatly simplified. Further help in bringing the base of the bladder up within reach might be secured by introducing two fingers into the vagina in women and pushing the anterior wall upwards.

At the conclusion of the operation, the bladder was closed with fine silk or catgut sutures, the investing fascia was also carefully united with catgut or silk, and the rest of the abdominal wound closed, in suitable cases leaving a small drain extending down to or into the bladder. By this operation a maximum exposure and accessibility of the bladder without injury to the important underlying structures was gained without a risk of subsequent hernia.

DISCUSSION.

Dr. J. Shelton Horsley, Richmond, Va., stated for more than a year he had been using the Pfannenstiel

incision as a routine measure in all suprapubic cystotomies, and he found it took very little more time than the ordinary incision and it left the abdominal wall in a much better condition afterwards.

DR. ERNST JONAS, of St. Louis, Mo., said the Pfannenstiel incision gave a very good view of the bladder. This incision had been advocated by Dr. Pfannenstiel for clean gynecological cases where there was no pus in the pelvis, and for cases in which the pelvis was badly infected.

DR. REUBEN PETERSON, of Ann Arbor, Mich., stated the Pfannenstiel incision was only suitable for clean cases. He had had a large experience with the transverse incision for shortening the round ligaments and for operations on the bladder, and if the wound should suppurate, the objection raised by Dr. Jonas held good. While the technic demonstrated by Dr. Kelly was fine for clean cases, he could see objection to this incision in suppurative cases.

DR. GEORGE H. NOBLE, of Atlanta, Ga., stated he had made use of the transverse or Pfannenstiel incision quite frequently in cases in which he did not expect to encounter a septic process, both in placing the uterus in its normal position and in opening the bladder. A point he wanted to bring out especially was, that in this dissection you could increase the opening very materially and satisfactorily by making a section of the lower ends of the recti muscles, where necessary, and get a good view. This was particularly the case where they wanted to open the pelvis to go into the peritoneum, using this incision.

DR. ALEXANDER HUGH FERGUSON, of Chicago, stated he could see how this method of exposing the inside of the bladder would be of great utility to those surgeons who practiced suprapubic prostatectomy also in removing papillomata in avoiding the ureter. They must remember that there was no fascia behind the rectus muscle in this region, and that it retracted easily and acted as a bar to infection in the operative area.

### STONE IN THE URETER.

DR. R. C. BRYAN, of Richmond, Va., reported eight cases of stone in the ureter, and then discussed the etiology, pathology, symptoms and diagnosis, differential diagnosis and surgical treatment. As to treatment, he said: The size, number and location of the stones having been accurately determined, the treatment resolved itself into one of two methods: (1) Ureteral catheterization and lavage; (2) operation. It would seem advisable in small stones, and those located in the lower segment of the ureter, to attempt by ureteral catheterization and injection to dislodge them. This would likely occur in a fair percentage of instances. It occurred in four of his cases. If this method failed, operation was indicated. He had done only the extraperitoneal operation. It did not appear that the intraperitoneal or combined methods offered any peculiar advantage which would justify the possibility of peritoneal infection by urine leaking from a suppurating tract. An incision starting midway between the highest point of the crest of the ilium and the eleventh rib and running to the anterior superior spine of the ilium, thence parallel with and internal to Poupart's ligament for its outer three fourths, had in his series given sufficient opening to explore the ureter from the kidney above to the bladder below. In those instances in which the stone was incarcerated in the intravesical segment, the incision might be carried down to the spine of the pubes, thus giving all the room desired. The ureter was cut through its long axis, the stone removed. Catgut sutures approximated the wound, and a tube was inserted to the site. In his series there was leakage in but one case for five days, the remainder giving none at the end of two days.

### THE EARLY DIAGNOSIS AND TREATMENT OF RENAL TUBERCULOSIS.

DR. J. M. MASON, of Birmingham, reported a case in which there was extensive tuberculous disease of the left kidney, with symptoms referable only to the bladder. He said renal tuberculosis was, in the beginning, a unilateral infection and might remain so for a long time. For successful treatment the patient should reach the surgeon while the disease was still confined to one kidney. The early symptoms were rarely referred to the kidney, but in a large percentage of cases were vesical and might remain so for many months. For the diagnosis, repeated examinations should be made for the detection of tubercle bacilli in the urine, and often the inoculation of guinea pigs should be resorted to. The cystoscope and ureteral catheters must be made use of to ascertain the condition of the bladder and to determine which kidney was the seat of disease, also for the purpose of ascertaining the organic and functional condition of the second kidney. The treatment consisted of prompt nephrectomy followed by the best hygienic, climatic and dietetic management.

### CÆSAREAN SECTION WITH SPECIAL REFERENCE TO THE TIME OF OPERATION AND ITS TECHNIC.

DR. LEWIS S. MCMURTRY, of Louisville, Ky., said the operation should be performed with the same deliberate care and expedition as were observed in other abdominal operations. There seemed to be a general impression on the part of surgeons that exceptional rapidity bordering on haste should characterise the steps of the operation. There was no valid reason for this. Davis made the abdominal incision above the umbilicus, and the uterine incision just below the fundus of that organ. The speaker did not believe the site of the incision was of essential importance. The abdominal wall at the full term of pregnancy was thin and relaxed easily. As soon as the abdominal incision was made and the uterus exposed, long gauze pads wrung out of warm salt solution were placed within the abdomen to hold back the omentum and intestines and protect peritoneal surfaces while the uterus was being emptied and closed. With the demonstrated results of Cæsarean section as now obtained the scope of the operation must necessarily be widened and its application greatly extended. What was most needed at the present time was an active interest on the part of all abdominal surgeons, and such a campaign of education as was successfully applied some years since in behalf of early operation in other conditions requiring prompt surgical intervention. It was established that the primary Cæsarean operation in skilled hands had a mortality quite as low as uncomplicated ovariotomy and clean hystero-myomectomy. With repeated examinations cervical dilatation and application of forceps carried out with crude and desultory observance of aseptic precautions, the mortality of abdominal hysterectomy was necessarily increased. The co-operation of the surgeon and the general practitioner was necessary to correct this fatal error.

### DISCUSSION.

DR. E. GUSTAV ZINKE, of Cincinnati, stated that if the mortality of Cæsarean section to-day was too high it was because of carelessness or indifference on the part of those who took obstetric cases and did not give them the attention they deserved. When a woman engaged their services with a view to attending her in

her approaching confinement they should study the case carefully. It was here where a mistake was made. Because a woman had a good shape, was otherwise in good health, and there was no indication of any difficulty, she was permitted to go until the time of labor had arrived, and the obstetrician in very many instances had not the remotest idea of the capacity of her pelvis or of the attitude of the fetus within the uterine cavity, and it was because of lack of this knowledge that the woman went into labor, and then labor was protracted from some cause or other, the difficulty of which was detected by the consultant, who saw the necessity of performing hebosteotomy, Cæsarean section, version or craniotomy, as the case might be. His sole object in speaking on this paper was to caution the profession anew, and he would do it on every possible occasion, that every case of pregnancy should be thoroughly studied before the woman went into labor. The physician should know all about her pelvis, about the attitude of the fetus, as well as the condition of her kidneys, heart, liver, etc.

Dr. Ernest S. Lewis, of New Orleans, said he thought the obstetrician should thoroughly examine every woman whom he expected to confine, not only to determine the presentation of the fetus, but to correct any malpresentation, if it was possible; also to determine the condition of the pelvis by proper mensuration. Statistics showed that Cæsarean section, the primary operation, was not attended with any more gravity than the removal of an ovarian tumor. He fully agreed with the author of the paper in regard to that, and that the danger was proportionate to the length of time the woman had been in labor, whether examined or not. There was greater danger of infection if frequent examinations had been made or if instruments had been used.

Dr. Reuben Peterson stated if there was one subject in the whole range of medicine that had been neglected in the last twenty years it was obstetrics. This could be explained in a way by the greater pecuniary rewards which had accrued to abdominal and other kinds of surgery, so that it had made the obstetric feature more or less anomalous in this country. Many men graduated from the medical schools without an accurate idea of what to do for a woman during pregnancy, or how to size up a difficult case before labor. The specialist was usually called in after the practitioner had failed to deliver the woman by the natural way. The time was coming when the operation of high forceps would not be taught in the medical schools as an obstetric procedure. High forceps were put on when the head had not entered the pelvic inlet. There was some disproportion between the head and the superior strait, and in his opinion Cæsarean section gave far better results to the woman and to the child than did the operation of high forceps.

Dr. McMurtry, in closing, stated the attitude of the profession towards Cæsarean section was a very serious one, and it should be corrected. It was the highest function of an association like this, whose expressions went out to the profession and were looked upon as authoritative, to correct erroneous impressions, and the erroneous impression he alluded to was the general attitude of the great body of medical practitioners, namely, that Cæsarean section should not be done until the patient had been examined by two or three men; that these examinations were made with the most perfect observance of asepsis, and all ordinary means of delivery had been tried on the patient for hours. The important point they wanted to impress was to get the great body of the profession to recognise early, if not before labor, early after labor had begun, that it was a case suitable for Cæsarean section.

### INTUSSUSCEPTION.

Dr. Stephen H. Watts, of Charlottesville, Va., reported two cases of intussusception in the adult, one of which was due to multiple adenomata of the intestine, and the other to a sarcoma of the cecum. In the first case it was found necessary at several operations to perform two resections of the intestine with lateral anastomosis, and seven enterotomies for removal of the growths. The patient was perfectly well when seen about a year after the last operation. In the second case, after reducing the intussusception, the sarcoma was removed with an elliptical portion of the wall of the cecum, and the patient made a good recovery. After reporting these cases, Dr. Watts discussed in some detail the symptoms, diagnosis and treatment of adenomata and sarcomata of the intestine.

### COMPLICATIONS DUE TO OPERATIVE PROCEDURES.

Dr. L. E. Burch, of Nashville, Tenn., mentioned the accidents following operative procedures in his own work, and referred to accidents occurring in the work of other surgeons. He laid stress on the following points: "(1) Many of the accidents following operations were preventable, while others were not. (2) No operation should be advised, however trivial in character, unless there is positive pathology to indicate its performance. (3) No operation should be carried out, either under local or general anesthesia, until a careful history of the case was obtained, including a thorough physical examination, with urinary and blood findings. (4) Better results would be obtained and fewer accidents would happen if patients were given preliminary treatment before operation. (5) Surgeons should never state to patients that any operation was free from danger."

### FORMATION OF A NEW VAGINA.

Dr. Alexander Hugh Ferguson, of Chicago, reported three cases. In the procedure presented the author did not claim to produce a normal vagina, still in two of the three cases reported a vagina had been formed which yielded satisfaction. The third case was not yet married, but there was no doubt but that the vagina would prove as efficient as the other two. The technic of the operation varied slightly in each case, but the underlying principles were the same, namely, first to utilise the available mucous membrane; second, to form three flaps; third, to tunnel through the peritoneum behind the bladder and in front of the rectum, dissecting the peritoneum from both structures without opening the peritoneal cavity; fourth, to invert the flaps into the tunnel thus formed and suture them in place with catgut. The lateral flaps included the mucosa of the labia minora on either side, exercising care not to interfere with the mucous membrane in connection with the clitoris and meatus urinarius. The central flap was cut as thick as possible in order not to interfere with nutrition. The lateral flaps were cut with the same precaution in mind. The fact that the flaps were not sutured together rendered the cavity dilatable to an ideal extent. Horse hair was used to close over the denuded areas. A roll of gauze about seven inches long was anointed with sterile vaseline and zinc oxide and inserted into the plastic vaginal canal. The external end spread like a flange and was held in place by a firm pad. It must not fit too tightly. As to the after-treatment, the initial dressing must not be withdrawn for six or eight days. The parts must be kept as aseptic as possible. The internal stitches were catgut and might be left to become absorbed. The horse hair should be left in place for two weeks. Abso-

lute cleanliness without antiseptics was of primary importance. The patient must remain under observation for at least three months.

### A POSITION FOR SAVING TIME IN COMBINED ABDOMINAL AND PELVIC OPERATIONS.

DR. A. C. SCOTT, of Temple, Tex., described this position as follows: By use of any metal knee-holder which fits comfortably in the popliteal space, one might secure a combined exposure of the abdomen in an elevated position, and at the same time exposure of the pelvic outlet, permitting the use of self-retaining specula, if desired. This was accomplished by having the popliteal knee-holder hinged on a short upright bar which was broadened and slotted at the lower end to slide, with a set screw upon a horizontal metal bar, which in turn was fixed to a strong cylindrical upright bar, sliding in a vise-like clasp at the side of the operating table. The sliding upon the horizontal bar allows adjustment for the varying lengths of patient's thighs. The cylindrical sliding upright bar at the side of the table permits the thighs to be moderately flexed or fully extended, abducted or adducted at will. Before starting the anesthetic, the patient's hips are brought beyond the edge of the table and the limbs placed upon the knee-holder. A piece of bandage loosely wound about each foot and ankle was tied to a convenient point below the corner of the movable part of the table to prevent extension of the leg; another was placed above each knee to prevent elevation of the knees, thus securely holding them in their respective knee-holders. Any modern operating table will serve the purpose for these attachments and enable one to secure the desired combined position if it had a pivotal point about the center permitting the entire surface of the table to be raised and lowered at will. He used a modification of the Markoe table which operated with wheel and ratchet and could be changed by the anesthetist with perfect ease. After the patient was in position and the anesthetic was begun, the foot of the table was lowered some five or six inches for convenience of completing the preparation by thorough rinsing of the abdomen and vagina. This was done and the table returned to the horizontal plane without again having to take hold of the patient with the hands.

The advantages of this position were: (1) Where two operators were working together with plenty of assistants at their command, the time required for many complicated operations might be reduced to a marked degree and often as much as 50%. (2) By changing the axis of the table, the pelvis and the abdomen might be lowered, if desired, or elevated to secure the advantages obtained by the Trendelenburg position at any stage of an abdominal operation without interfering with work simultaneously being done upon or through the pelvic outlet. (3) All the advantages of the Trendelenburg position might be obtained without its disadvantages. (4) All the advantages of the dorsal position for pelvic outlet work were obtained without flexing the thighs upon the abdomen or otherwise interfering with work required through the abdominal wall. (5) The final preparation of rinsing both the abdomen and vagina was easily accomplished while the anesthetic was being given without having to lift or disturb the patient again. (6) By wide abduction of the extended thighs during abdominal operations room was made for a second assistant to stand with advantage for sponging, ligating and retracting equal to the one standing directly across the table from the operator.

### THE TREATMENT OF ANTEFLEXION.

DR. HENRY T. BYFORD, of Chicago, stated he did not offer a new treatment. He asserted that the newest methods were not satisfactory and selected for consideration one of the old methods and gave the essentials and technic that had given success in his practice. The method consisted in keeping the cervix overdilated for six months to a year, and in the prevention, during the second year, of contraction sufficient to cause symptoms. The advantage of this method over all others consisted in keeping the uterus under the influence of the treatment until the cervix developed to a size that would not interfere with uterine drainage and cause symptoms, when the case could be compared to those of symptomless rigid anteflexion that we sometimes observed in multiparæ. He claimed that the cutting operations favored atrophy of the cervix and were irrational in most cases because the cervix was already deficient in development.

### COMPLETE TRANSVERSE DESTRUCTION OF THE SPINAL CORD.

DR. RANDOLPH WINSLOW, of Baltimore, read a paper in which he reported a case of complete transverse destruction of the spinal cord from pistol wound without penetration of the spinal canal; with a consideration of concussion as an etiological factor in the production of this lesion, and of the question of suturing the cord when it was completely divided. He narrated two cases of pistol wound of the dorsal vertebræ in which the cord was not injured by direct impact of the bullet, but in both of which paralysis and the usual signs of a transverse destruction of the cord immediately supervened, proving fatal in one case, which came to autopsy and the bullet was found lodged in the second dorsal vertebra, but not penetrating into the spinal canal or impinging on the cord. The other case presented similar symptoms and was submitted to laminectomy, but the cord was not divided nor could the missile be found. He was still living, but was in a very precarious condition, with absolute paralysis below the eighth dorsal vertebra. These cases were thought to have been due to concussion of the cord. The views of a number of military surgeons and authors were quoted in regard to the production of the lesions of the cord by concussion without direct impact on the spinal cord, who were unanimous in the belief that such injuries did occur. The question of suturing the severed spinal cord was discussed, and several operations of this character in the hands of other surgeons were mentioned. The results had not been good, and physiologists declared that regeneration of the severed spinal cord was impossible. Be this as it may, marked improvement followed in one case, and there was no reason why the cord should not be sutured in appropriate cases. Dr. Winslow summed up his views upon these questions as follows: (1) That serious and even fatal lesions of the spinal cord might be produced by concussion, without direct impact. (2) That in gunshot injuries with a probability of a complete severance of the cord, laminectomy should be performed, foreign bodies and clots removed, bleeding arrested, and if the cord had been divided, the separated ends should be approximated with sutures. (3) Care should be exercised not to destroy any nerve fibers or tracts which might still be intact.

### AN UNUSUALLY LARGE OVARIAN CYST.

DR. J. SHELTON HORSLEY, of Richmond, Va., reported a case (and showed photographs) of a large ovarian cyst which weighed 116½ lb. The greatest abdominal circumference was 63 inches. It was successfully removed. He referred to the fact that operation in these cases of large ovarian cysts usually had a

high mortality rate on account of the pressure which caused organic changes and made the patients poor surgical risks.

DISCUSSION.

Dr. Thomas S. Cullen, of Baltimore, Md., stated four and a half years ago he saw a patient who weighed 174 lb. She was supposed to have had an ovarian cyst, but it turned out to be a fibroid tumor. They operated, removed an 89-lb. fibroid, and the patient immediately after operation weighed 85 lb. After a week in the hospital, when edema began, she weighed 80½ lb., and although she developed bed sores, she promptly recovered. In that case after operation the ribs stuck out six inches and the recti muscles which lay high up on either side gradually came together until at the present time they were only 2 cm. apart.

Dr. Alexander Hugh Ferguson stated he was called to a small town near Indianapolis to see a woman with a large ovarian cyst. She had carcinoma of the left breast and gallstones. She was in a bad condition. He introduced a small trocar and canula which went into a cyst that was quite watery. The trocar was left in place for twenty-four hours. The next day she was able to eat, a thing she had not been able to do for two weeks, and was able to swallow. Her heart, which was bad, improved. He passed a large trocar in another direction through the same opening, and allowed it to remain for another twenty-four hours, and then she was brought to Chicago, and three days later he operated and at one sitting removed the cyst, the left breast and 1,250 gallstones from the gall bladder, and she recovered.

*(To be continued.)*

## Book Reviews.

*The Principles of Gynecology.* By W. Blair Bell, B.S., M.D. Lond., Assistant Gynecological Surgeon, Royal Infirmary, Liverpool. With 6 colored plates and 357 illustrations in the text. London, New York, Bombay and Calcutta: Longmans, Green & Co. 1910.

This is a clearly printed, well-bound and satisfactorily illustrated book of 551 pages representing the author's experience in the Royal Infirmary in Liverpool. All references to the literature and, therefore, proper names have been omitted because of the author's belief that they are not needed in a textbook for students and the general practitioner. An attempt has been made to adopt a simpler and more logical arrangement than is found in the time-worn treatises on gynecology. The book opens with excellent chapters on the development and the anatomy and physiology of the genital organs. The photomicrographs are especially good here, and the many examples found elsewhere are a strong feature of the book. The chapter on case taking and the examination leaves something to be desired in that the positions of the patient and the physician in the examination are figured faultily in the case of both the dorsal and the Sims position. The titles of the succeeding chapters show the author's somewhat unusual classification: "Congenital derangement of the normal anatomical conditions — malformations; Acquired derangements of the normal anatomical conditions — injuries; Acquired derangements of the normal anatomical conditions — displacements; Disorders of the normal physiological conditions in relation to menstruation; Disorders of the normal physiological conditions in relation to conception; Infective and parasitic diseases of the genital tract; Retention and effusion cysts of the genital tract; Innocent neoplasms of the genital tract; Malignant neoplasms of the genital tract; The preparations for operation and the subsequent management of the case; The main principles of gynecological operations, with some details of their technic." One appendix considers electrotherapeutics in gynecology and another, the classification of the causes of certain symptoms. An excellent index with the chief references in dark type closes the book.

Chapter VII, treating of displacements and the use of pessaries, is not satisfactory from the standpoint of the American gynecologist, particularly as to the handling of pessaries, although the advice as to the choice of operative procedures for the correction of displacements is sound. As much cannot be said of the plastic operations recommended and figured in the later chapters. For instance, Pozzi's operation for congenital stenosis of the cervix and the form of amputation of the cervix, figured on pages 496–498, have been too little proven to justify recommending them to students, and the borrowed figures of plastic operations on the pelvic floor and the figures of the operation for vesico-vaginal fistula are too diagrammatical to show properly the steps taken. Any conservative operator would question the advisability of sewing the bladder to the abdominal wound in performing hysteropexy as shown in Figure 312, on page 462. There are several good colored plates and the illustrations, as a whole, are well executed. The book is to be commended as an able exposition to the student of gynecology from a new point of view.

*Diagnosis and Treatment of Diseases of Women.* By Harry Sturgeon Crossen, M.D., Professor of Clinical Gynecology, Washington University; Gynecologist to Washington University Hospital and Director of the Gynecological Clinic; Gynecologist to St. Louis Mullanphy Hospital, etc. Second edition, revised and enlarged. With 744 engravings. St. Louis: C. V. Mosby Company. 1910.

This second edition, as far as page 685, with the exception of an added list of illustrations and a regrouping of the figures in the first forty pages, is identically the same page for page as the first edition, a review of which was published in this Journal, Jan. 9, 1908.

The book now has 1,025 pages instead of 799, and 744 illustrations as against 700, but, on account of the thinner glazed paper upon which it is printed, the volume is no larger than the first.

Following page 685, where are to be found some additions to the treatment of malignant diseases of the uterus, there are abundant evidences of a thorough revision and amplification. The chapter

on pelvic inflammation has much new matter and new illustrations. Some of the latter are especially good, notably Figure 631, showing the connective tissue of the pelvis, and Figures 634 to 640, illustrating the opening and draining of a pelvic abscess. This chapter and the section on extra-uterine pregnancy in the following chapter are most satisfactory expositions of these subjects. The chapters on tumors of the ovary and parovarium and on malformations have been rewritten and illustrated anew, and the same may be said of the chapter on disturbances of function. The use of stem pessaries has been introduced into the treatment of dysmenorrhea in the virgin, and intermenstrual pain, precocious and vicarious menstruation receive more adequate treatment. The author has introduced into the chapter on the invasion of the abdominal cavity some new figures to explain his method of caring for gauze strip sponges during abdominal operations, and has inserted into the same chapter eight pages of tables of reported cases of foreign bodies lost in the abdominal cavity. The chapter on medico-legal points in gynecology has been enlarged. The index now consists of thirty-three double column pages compared with less than seven four-column pages in the first edition, and is much more useful.

As was said in the review of the first edition, the book abounds in useful practical points in technic. This edition is better than the first. It would be still further improved if a lot of the illustrations which show very little were omitted and others, which are crowded together and thus separate the text, such as those on pages 202 to 209, 212 to 218 and 245 to 251, all of these pages containing no text at all, were distributed.

*A Treatise on Orthopedic Surgery.* By ROYAL WHITMAN, M.D. Fourth edition. Lea & Febiger. 1910.

This excellent work has rapidly reached a fourth edition, demonstrating both the value of the treatise and a general interest in the subject. The third edition was so complete that the author has not found it necessary to make many changes in the latest publication. The book is of standard quality, both in text and appearance.

*Sanitary Statistics of the Italian Navy for the Years 1905–1906.* Rome: Ludovico Cecchini. 1910.

This belated biennial report of the Italian naval health inspector to the Minister of the Marine presents interesting tabulation of the incidence and duration of diseases among sailors in the Royal Italian Navy during the period noted. It is instructive to observe that in each year the minimal incidence of both syphilis and gonorrhea occurred in December. As the inspector remarks in his comment: "The cold of this month is not propitious for vagabond affections."

*Pellagra.* By DR. A. MARIE. With Introductory Notes by PROFESSOR LOMBROSO. Authorized translation from the French by C. H. LAVINDER, M.D., and J. W. BABCOCK, M.D. With additions, illustrations, bibliography and appendices. Columbia, S. C.: The State Company. 1910.

Dr. Marie's monograph on pellagra, of which the present volume is a translation and adaptation, is itself an abridgment of Lombroso's extensive treatise on the same subject. The latter was by general consent the leading authority in the world on pellagra, to which he had devoted much time in study and great skill in scientific research; and in selecting for presentation to the American profession the French version of his work, the translators have acted with great good judgment. Their work of translation and revision has been well done and affords an admirable example of comparative literary study in medical science, a kind of work which is nowadays unfortunately rare. There is an excellent prefatory note by Lombroso, written for this translation shortly before his death. There has hitherto been no good treatise in English on pellagra. This book supplies that defect and should constitute a valuable contribution to the materials and data now being accumulated for the study and ultimate eradication of the disease in this country.

*Diseases of the Eye, a Handbook of Ophthalmic Practice.* By G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology, University of Pennsylvania. With 351 illustrations and seven chromolithographic plates. Sixth revised edition. Philadelphia: W. B. Saunders Company. 1910.

Certain portions of the book have been largely rewritten; for example, parts of the chapters on Cataract, Diseases of the Retina, and Glaucoma; Iritis and its Manifestations; the Pathogenesis of Sympathetic Ophthalmia; Intra-ocular Optic Nerve Inflammation (Optic Neuritis) and Edema (Choked Disc, Papilledema); Nystagmus; Pulsating Exophthalmos; the Operations for Ptosis and Orbital Operations, which will no doubt enable this edition of the work to maintain its well-known position as a textbook on ophthalmology.

*Modern Materia Medica and Therapeutics.* By A. A. STEVENS, A.M., M.D. Fifth edition. Philadelphia and London: W. B. Saunders Company. 1910.

As the title indicates, this is a work on materia medica and therapeutics and not on pharmacology. The amount and quality of the latter given under "Physiologic Action" is not always up to the present standard. The book is divided into two parts, the first considering the drugs with their properties and uses, while the second portion deals with diseases and their treatment. The latter section is somewhat more valuable than the first, yet it is not wholly up to date, and especially the chapters dealing with gastro-intestinal diseases. However, both students and practitioners may derive from it some convenient information.

*Extra Pharmacopea.* By W. H. MARTINDALE, Ph.D., F.C.S., and W. W. WESTCOTT, M.B., D.P.H. Fourteenth edition. London: H. K. Lewis. 1910.

We hold the same favorable view towards this small volume as towards a previous edition of the same. It contains an immense amount of very valuable pharmaceutic and therapeutic information. This edition is enriched by new chapters on lactic acid bacilli, organic arsenic compounds, ionphoresis, radium, etc.; in the back of the book, as in the previous edition, there is a valuable chapter on clinico-chemical tests in urine, stomach contents, etc.

*Nephrocoloptosis.* A Description of the Nephrocolic Ligament and its Action in the Causation of Nephroptosis, with the Technic of the Operation of Nephrocolopexy, in which the Nephrocolic Ligament is Utilized to Immobilize both Kidney and Bowel. By H. W. LONGYEAR, M.D., Professor of Gynecology and Abdominal Surgery, Detroit Post-Graduate Medical School; Clinical Professor of Gynecology, Detroit College of Medicine; Gynecologist to Harper Hospital; Consulting Obstetrician to the Woman's Hospital; Ex-President of the American Association of Obstetricians and Gynecologists. With 88 special illustrations and a colored frontispiece. St. Louis: C. V. Mosby Company. 1910.

In this suggestive little book Longyear takes up broadly one of the features of the now popular topic of abdominal ptosis, and writes himself down as a pioneer investigator. Doubtless he is so. The book is suggestive if not always convincing. The main feature of the book is a dealing with the description of a ligament little regarded by, or unknown to, the average surgeon, a structure which some may think hypothetical, — the nephrocolic ligament, which the author describes as a definite band of tissue connecting the kidney capsule with the colon. This statement alone suggests the nature of the argument and the character of the book. A ligament closely connecting these two organs makes inevitable the conclusions drawn by the author, namely, that a descent of the caput coli and the ascending colon must bring down with them the right kidney. Granted these premises, one sees how an extremely perplexing and difficult problem in surgery may be solved. Since a descent of the colon, which we now know to be common, involves a descent of the kidney, we turn at once to certain inevitable measures of treatment. We conclude that the mere fixation of the kidney, as has been done for so many years, must be mainly futile unless the colon also be elevated and held in place. To accomplish this, Longyear advocates various measures, mainly the application of certain ingenious confining apparatus, or harness, supplemented, when necessary, by his method of fixing the kidney through operation. We commend the book to the reading of surgeons concerned in this problem.

## THE ECONOMIC ARGUMENT IN PREVENTIVE MEDICINE.

IN various campaigns of popular education on topics of public health and preventive medicine we have lately become familiarized with the so-called economic argument, which is in substance that every case of sickness or death represents a pecuniary loss to the community and that, therefore, the prevention of sickness and death represents a pecuniary gain, or at least saving. It is probably true that in the long run it costs less to prevent disease than it does to cure it; so far the argument is sound. But there seems a possible element of fallacy in the inference that a life saved is necessarily a financial asset to the state.

There have been numerous recent instances of the use of this form of argument. For instance, in his address on "Good Vision as an Economic Asset," to which we refer in another column of this issue, Dr. Lewis makes the assertion that the 2,000 cases of preventable blindness among the 6,000 blind persons in New York state represent a loss in capital of $28,000,000. This statement is based on the assumption that the individual human life has a measurable economic value, representing its average earning capacity. For this value various figures are set, depending on the nature of the statistician and the community from which the statistics are computed. Dr. Lewis estimates it at $14,000. A bulletin recently issued by the California State Board of Health sets the commercial value of the average male of thirty years at $16,000. The loss of every such life is supposed to represent a loss of that amount to the community.

There is undoubtedly an element of truth in this argument, but there is also an element of error. Human life is not altogether measurable,

even economically, in dollars and cents. Many lives are worth much more to the community than their earning capacity, many are worth much less. Moreover, even the economic value of human life is purely potential. If a man dies, whose supposed commercial value is $16,000, his death does not take that amount in cash out of the public treasury, nor would his continued existence necessarily mean more than his ability to take care of himself on the income of his intangible capital. Ethically, human life is of immeasurable value; but economically it is often as cheap as the individual life is everywhere in nature. President Eliot said in his Ether Address two years ago: "A baby is at its best only a hope." As a hope its value is infinite; as a financial asset it is probably not worth even the $2,500 at which a Massachusetts educator has recently appraised it. So in Dr. Lewis's 2,000 cases of preventable blindness, the economic loss which they involve to the state should be reckoned in terms rather of the actual public cost of their maintenance than of their hypothetical value as invested capital.

Our reflections on this subject should not be construed as aiming to abate an iota of public or professional zeal in the relief of human suffering by prevention. They are intended merely to point out a possible fallacy in the economic argument of which so much has lately been made. The campaigns of preventive medicine should be and are waged on much more altruistic grounds, and the use of such an argument will hardly be of great value even with those to whom it is intended to appeal, especially if not standing the test of an ultimate analysis.

## THE CASE OF THE MIDWIFE.

THERE is now before the Massachusetts Legislature a proposed act providing such amendments in the existing law relative to the reporting of births in this state as shall make the record of data more complete and their return more prompt. The intent and general purport of this act are excellent, but one of its details seems undesirable. In section 3, which provides the penalty for failure to report births within a specified time, there is used throughout the phrase "physician or midwife." Though this is not perhaps in itself important, it does, however, in effect, place physicians and midwives on a plane of equality to which the latter ought not to be admitted.

In another column of this issue we publish an extensive "Review of the Midwife Situation," by Drs. Emmons and Huntington, both of whom have had excellent recent opportunity to study this problem at home and abroad. The experience of foreign countries seems to indicate that the midwife, even when licensed and controlled, is always a source of possible danger to the community. The same is true in the United States. A recent investigation in Ohio, for instance, showed that over 50% of the midwives practicing there use no prophylactic measure against ophthalmia neonatorum. The essential inconsistency of simultaneous practice in a community by obstetricians and by midwives is that it involves a divided responsibility and a double standard of efficiency. The midwife may be defined as a person attempting to practice obstetrics without complete or even adequate medical education. The tolerance of such persons is an anomaly in an enlightened civilization. The midwife is a relic of medievalism, unhappily extant in the countries of the old world, but whose persistence in our own community should not be encouraged by any form of recognition.

## DETERMINATION AND NUMERICAL RELATIONS OF SEX.

THE factors governing determination of sex have long been a subject of rather inconclusive speculation. An editorial in the issue of the *British Medical Journal* for Feb. 4 comments interestingly on a recent article in *Nature* by Dr. R. J. Ewart on the numerical relation of the sexes. It is well known that male births exceed female, and at present this excess in Great Britain is in the ratio of 1,033 to 1,000. This ratio is maintained with a fair degree of constancy in all civilized countries, except under collateral conditions of war and famine, when the male birth-rate rises. The greater mortality of males, however, leads to an aggregate excess of females. From examination of vital statistics, Dr. Ewart believes he has discovered that women under twenty-five tend to produce female children; women over twenty-five, males. As a result, when there is an excess of females, more women will not marry till after twenty-five and an increase of males will result. Then more women will marry early, and the excess of females will be restored. There will thus be a series of slow oscillations on either side of an even balance between the sexes.

Dr. Ewart considers that the world's population is now at the zenith of a female fluctuation. Unfortunately no reliable statistics are available

over a long enough period to prove this point. Whatever the truth of his surmises, his conclusions seem to have little bearing on the moot question of sex determination, in which, from a purely objective point of view, temperament seems to play a larger part than any determinable physical factor.

## THE DEATH-RATE OF LONDON.

The vital statistics of London, as the largest civilized community in the world, are of particular interest and importance in showing what modern sanitary and preventive medicine can do to mitigate the hygiene evils of city life. The annual report of the Medical Officer of Health for the London County Council for 1909 shows the death-rate in that year to have been 14 per 1,000 living at all ages. Only two large cities in the world had a lower total mortality figure that year, Amsterdam and Brussels; and only two had a lower infant mortality, Amsterdam and Stockholm. In London only four diseases showed an increased death-rate over the preceding year, measles, influenza, pneumonia and cancer. The cancer death-rate has increased steadily since 1851. The total mortality percentage for 1910 has not yet been published, but during the last four months of the year it was respectively, 11.9, 12.6, 17.4 and 15.8 per 1,000, corresponding to an average of 14.4 for those months. It is interesting to note that the rates vary widely in the different districts and boroughs, the highest being 23.0 in Finsbury and 20.6 in Shoreditch, in the heart of the city; the lowest, 11.7 in Fulham and 11.9, Greenwich, at its periphery. Such figures indicate that the mortality in a large city is a composite of many factors and does not necessarily represent universal good health in a homogeneous population.

## OPTOMETRY.

Our recent editorial respecting the claims of opticians to recognition as "optometrists" is called to our attention by the receipt of a *Bulletin* of the American Medical Association devoted entirely to this subject. This bulletin is a continuation and extension of articles on the same subject by Dr. John C. Bossidy published in this Journal, Jan. 16 and Feb. 13, 1908. It shows beyond doubt that these men preach medicine in their meetings, teach it in their schools, that their legislative agitation centers around the legal recognition of that word "optometry."

The most striking part of the article is that which reproduces medical questions asked by their boards of examiners in optometry in states which have legislated in their favor. The *Bulletin* shows also that Vermont and Maine have arranged to examine candidates in anatomy, physiology and pathology of the eye, while Rhode Island's medical questions are given *in extenso*.

The hearing on this bill will be before the Committee on Public Health on March 9. Medical men are urged to attend, and thereby show their interest in protecting the profession and the people.

## MEDICAL NOTES.

Two Centenarians. — William J. Frazier, who died on Feb. 12 at Aurora, Ill., was locally reputed to have been born in 1810.

Henry Parminter, who died on Feb. 15 at Charlotte, N. C., is said to have been born on March 2, 1803. His wife died in 1909, at the alleged age of one hundred and one. He is survived by several great-great-grandchildren.

Accidental Death of a Centenarian. — It is reported from Florence, Colo., that on Feb. 15 Mrs. Francis Esper, of that town, alleged to be one hundred and eight years of age, died of burns received from the accidental ignition of her clothing by an open fire. She is survived by her husband, reputed to be three years her senior. They are said to have been married ninety-one years ago. It seems unfortunate that so distressing an accident should have prematurely terminated such a period of marital felicity.

A Devonshire Superstition. — Devonshire, in England, seems to be a particularly favorable spot for the survival of interesting popular medical superstitions. One of these, narrated in the Bristol *Times*, is that if a live spider be imprisoned in a nutshell and hung around the neck of a child with whooping-cough, the disease will disappear when the spider dies. Judging from the apparent persistent vitality of starveling spiders in attics and cellars, it should seem that their endurance under these circumstances would about equal the naturally self-limited course of pertussis.

Physicians' Fees and Penalties. — Physicians nowadays who are prone to complain that fees are small and that many patients fail to pay their bills should remember that, though some recorded fees in older times were large, the status of the recipient was hardly as enviable

as that of the modern doctor.. Dr. Walsh, of New York, has recently commented on a provision of King Hammurabi, of Babylon, B.C. 2250, that "if a physician operated on a man and save the man's life, he shall receive ten shekels of silver; but if he cause the man's death, they shall cut off his fingers." Perhaps, however, the modern malpractise suit, which has taken the place of the latter penalty, is even more to be dreaded than personal mutilation.

CORINNA BORDEN KEEN RESEARCH FELLOWSHIP OF JEFFERSON MEDICAL COLLEGE. — The accumulated income of this fund now amounts to $1,000. The fellowship will be awarded by the trustees, upon recommendation of the faculty, to a graduate of the Jefferson Medical College of not less than one nor more than ten years' standing, upon condition that he shall spend at least one year in Europe, America or elsewhere, wherever he can obtain the best facilities for research in the line of work he shall select, after consultation with the faculty; and that he shall publish at least one paper embodying the results of his work as the "Corinna Borden Keen Research Fellow of the Jefferson Medical College." Aspirants may address Dr. J. W. Holland, Dean.

THERAPEUTIC "BAKING" IN ENGLAND. — In the issue of the *Lancet* for Dec. 10, 1910, page 1705, a review of Vol. VII of Bryant and Buck's "American Practice of Surgery," commenting favorably on the chapter by Drs. Porter and Quinby, of Boston, on "Surgical Diseases of the Extremities," concludes as follows: "On one point we should like an explanation. For hematoma of the quadriceps femoris the following treatment is given: 'The patient should be kept at rest in bed for the first few days, and baking and moderate bandaging should be employed.' We do not understand what is meant by 'baking.'"

Evidently the application of dry heat to joints and limbs by means of specially constructed portable ovens within which the part may be placed is known in England by some other term than "baking," for it is inconceivable that so well-established a therapeutic procedure should be unfamiliar to physicians in that country.

## BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 21, 1911, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 40, scarlatina 36, typhoid fever 3, measles 101, smallpox 0, tuberculosis 69.

The death-rate of the reported deaths for the week ending Feb. 21, 1911, was 20.13.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, noon, Feb. 18, 1911, was 265, against 262 the corresponding week of last year, showing an increase of 3 deaths, and making the death-rate for the week, 20.06. Of this number 118 were males and 147 were females; 258 were white and 7 colored; 151 were born in the United States, 109 in foreign countries and 5 unknown; 58 were of American parentage, 173 of foreign parentage and 34 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 47 cases and 2 deaths; scarlatina, 43 cases and 0 deaths; typhoid fever, 4 cases and 0 deaths; measles, 96 cases and 2 deaths; tuberculosis, 55 cases and 33 deaths; smallpox, 0 cases and 0 deaths. The deaths from pneumonia were 65, whooping cough 5, heart disease 40, bronchitis 5. There were 14 deaths from violent causes. The number of children who died under one year was 46; the number under five years, 64. The number of persons who died over sixty years of age was 89. The deaths in public institutions were 105.

APPOINTMENT OF DR. CARSON. — It was announced last week that Dr. Paul Carson, who since 1894 has been port physician in charge of the quarantine station in Boston harbor, has been appointed as chief of the newly established division of child hygiene and school medical inspection of the Boston Board of Health. It is stated that the number of school medical inspectors is to remain eighty, as at present, but that the salary of each of these physicians is to be increased to $500.

SEIZURE OF CATSUP AT BOSTON. — On Feb. 13, at Boston, the United States deputy marshal made a seizure of thirty barrels, containing a total of fifteen hundred gallons, of tomato catsup, valued at three hundred dollars. This catsup, which is part of a large consignment from a New York firm, is declared by government officials to be made of "canners' waste," and, therefore, unfit for consumption under the provisions of the pure food law.

TWO BEQUESTS FOR HOSPITALS. — It was announced last week by the executor of the estate of the late John G. Aborn, of Wakefield, Mass., that the latter had bequeathed to the town a

tract of two and one-tenth acres of land overlooking Lake Quannapowitt, to be used as the site for a general hospital and a home for aged men.

The will of the late Alice M. Curtis, of Wellesley, Mass., filed last week for probate in the Norfolk Probate Registry at Dedham, Mass., contains a bequest of $20,000 to the New England Hospital for Women and Children, the income to be used for the support of free beds. This hospital is also made one of three beneficiaries under a residuary fund.

Anti-Vivisection Exhibit in Boston. — It is announced that there is to be held in Boston next week by the New England Anti-Vivisection Society, "a loan exhibit displaying the appliances and picturing the inhumanity of vivisection." On March 1, in Lorimer Hall, Dr. Herbert Snow, of England, is to lecture on the subject of the anti-vivisection crusade. This exhibit and, if possible, the lecture, should be attended by physicians interested in the safeguarding of legitimate animal experimentation, for the purpose of becoming familiar with both the arguments and the misrepresentations of the anti-vivisectionists, which must be intelligently controverted and exposed in the defense of scientific methods of inquiry.

Accidental and Intentional Trauma by Hatpins. — On Feb. 13 Capt. Andrew Englund, of Portland, Me., died in the Boston City Hospital of facial erysipelas, alleged to have developed at the site of several scratches accidentally received on Jan. 15 from the hatpin of a passenger beside whom he was riding in a street car. Though it is perhaps unfair to attribute this death directly to the injuries by the hatpin, the episode calls attention to another of the dangerous possibilities of that implement, hitherto chiefly familiar to surgeons as a perforative weapon of defense.

Meeting on the Prevention of Blindness. — At a meeting held in Boston on Feb. 14 by the Massachusetts Association for Promoting the Interests of the Blind, the principal address was delivered by Dr. F. Park Lewis, of Buffalo, N. Y., chairman of the committee of the American Medical Association on the prevention of blindness, who spoke on "Good Vision as an Economic Asset." Other addresses were made by Mr. James P. Munroe, chairman of the Massachusetts State Commission for the Blind; by Mr. Henry C. Greene; by Dr. Mark W. Richardson, secretary of the Massachusetts State Board of Health; by Miss Helen Keller; and by Dr. David Snedden, commissioner of education for Massachusetts.

Two Proposed Pieces of Legislation. — A resolve has been introduced before the Massachusetts Legislature providing "that there be allowed and paid out of the treasury of the commonwealth to the trustees of the Massachusetts Homœopathic Hospital in Massachusetts, the sum of fifty thousand dollars for the extension and enlargement of its buildings and for the maintenance of said hospital." This proposed measure has been referred to the House committee on public charitable institutions.

Another bill brought before the legislature provides for the licensing by local police departments of such persons as "practice manicuring or massage or conduct an establishment for the giving of vapor baths for hire or reward." The bill gives to members of police departments "the right to enter and inspect premises" in which such employments are conducted, and provides fine or imprisonment as a penalty for interference with this right or for the practice of such occupations without a license. This measure has been referred to the House committee on public health.

Annual Meeting, Boston City Hospital Alumni Association. — The annual meeting of the Boston City Hospital Alumni Association was held on Wednesday, Feb. 15, 1911.

In the morning, medical and surgical cases were shown in the amphitheater of the hospital, after which a luncheon was given to the members by the trustees.

The annual business meeting was held at the Hotel Vendome at 6.30 o'clock. The following officers were elected for the year 1911–1912:

President, Dr. Henry W. Broughton, of Jamaica Plain; Vice-President, Dr. Hayward W. Cushing, of Boston; Secretary, Dr. William H. Robey, Jr., of Boston; Treasurer, Dr. William R. P. Emerson, of Boston; Member of the Executive Committee for five years, Dr. Charles H. Hare, of Boston.

The President, Dr. George T. Tuttle, of Waverley, presided at the post-prandial exercises and introduced the following speakers:

Mr. A. Shuman, President of the Board of Trustees; Dr. Francis B. Harrington, of the Massachusetts General Hospital; Dr. Charles W. Eliot, of Harvard University; Arthur D. Hill, Esq., of the Suffolk Bar; Dr. Henry W. Broughton, President-Elect.

Mr. A. Shuman was made an honorary member of the association.

One hundred and five members were present.

NEW YORK.

ENLARGEMENT OF SKIN AND CANCER HOSPITAL. — At the New York Skin and Cancer Hospital, on Feb. 17, the newly completed wards for advanced cases and the new nurses' home were thrown open for public inspection. The recently installed fulguration apparatus of Dr. Keating Hart, of Paris, and other new electrical appliances were also exhibited.

STATE RESERVATION AT SARATOGA SPRINGS. — In carrying out the plan of establishing a state reservation at Saratoga Springs, for which the Legislature in 1909 appropriated $600,000, the Reservation Commission, on Feb. 16, filed with the proper officers documents preliminary to acquiring three of the spring properties, with an adjoining tract of land. The springs condemned in order that a price may be fixed for their purchase are the Hathorn 1 and 2 and the Carlsbad.

CAMPAIGN AGAINST TUBERCULOSIS. — On Feb. 13 a mass meeting in the interests of the campaign against tuberculosis was held at the Academy of Music, Brooklyn, under the auspices of the Brooklyn Bureau of Charities. A number of addresses were made, and a series of stereopticon pictures were presented, showing tenement-house conditions previous to the passage of correcting laws, some bad conditions still existing, and the improvements which had been and were being made in housing conditions.

TUBERCULOSIS IN PRISONS. — At the meeting of the Society of Medical Jurisprudence on Feb. 13, Dr. J. B. Ransom, physician to the Clinton Prison at Dannemora, N. Y., gave an address on "Tuberculosis in Prisons." There was no greater error, he said, than to suppose that, because of the isolation of these institutions, tuberculosis in their inmates does not constitute a grave danger to society at large. There were 20,000 tuberculous prisoners in the penal institutions of the United States, and the vast majority of these, when liberated, returned to that portion of the community in which tuberculosis is most quickly and virulently spread. The statistics presented by Dr. Ransom showed that 60% of all deaths in the prisons of the world are due to this disease, and that at times the mortality has reached 80%. Tuberculosis is much more prevalent among the inmates of the prisons in the Atlantic and Middle West states than among prisoners in the Southern and Western states; a condition due to the fact that the latter are put to work in the open air. Of the 5,000 prisoners in New York state, no less than 1,000 are the subjects of tuberculosis. Still, the speaker said, considerable gain had now been made by intelligent treatment, and at Clinton Prison the percentage of mortality among tuberculous patients had been reduced from 2,021 per 100,000 in 1891 to 160 per 100,000 in 1910. Having referred to the efforts at combatting the disease elsewhere, he urged the necessity of a systematic campaign for the treatment of tuberculous inmates of prisons and other public institutions, advocating as most important the establishment of special sanitariums and the providing of outdoor work.

CHRISTIAN SCIENCE HEALER HELD FOR TRIAL. — For the first time in New York a Christian Science healer has been brought to book for the illegal practice of medicine. Willis V. Cole, a practitioner of this class, maintaining a suite of offices on Fifth Avenue, had been summonsed to court by the County Medical Society on the charge of violating a section of the public health law, and on Feb. 11, in the Tombs police court, Magistrate Freschi held him for trial in the Court of Special Sessions. In concluding an extended opinion the magistrate said: "In view of all the circumstances of this case I am of the opinion that the practice of the treatment of disease by inaudible prayers, as taught by the book of Mrs. Eddy, violates the law of this state. The only thing on which the defendant can claim any right to practice as a 'healer' of disease is that the exception in the public health law excludes him from the operation of the definition of 'the practice of medicine.' [The law states that the definition given shall not be construed to affect the practice of the religious tenets of any church.] The Christian Scientist has the right to believe that he can heal by prayer, but I am of the opinion that if he carries and puts this belief into practice for hire, and solicits patients by advertisements, then he exceeds his rights under the law and comes directly within the prohibition contained in Article III of the Constitution of the State of New York. He must subordinate his belief to the rights of the community and the state as an entity when the exercise of that belief either impairs or endangers the health of the people or tends to place their health in jeopardy, so that the safety of the state will be affected." If Cole should be adjudged guilty in the Court of Special Sessions, the case will undoubtedly be appealed, as the matter is, of course, one of vital importance to the Eddyites.

7. Clurman, M. J. *The American Game of Football: Is It a Factor for Good or for Evil?*

6. Wallace emphasises the danger of using diphtheria antitoxin or any other form of horse serum in individuals with unstable vasomotor systems and in those subject to asthma, hay fever and bronchitis. It is in such persons that we see serum disease and rarely sudden death after injection. The administration hypodermically of aqueous extracts of the suprarenal glands previous to the use of serum in this class of cases is desirable in order to rehabilitate and control the vasomotor system, and may prove of great prophylactic value as well as useful in the emergency of an acute attack of serum disease. 7. Crothers, T. D. *Inebriety: Its Treatment and Curability.*

3. Weber reports a desperate case of pneumonia in which he used hypodermic injections of camphorated oil. One dram of a freshly prepared solution, 20% camphor in oil of sweet almonds, was injected into the outer circumference of the thighs every hour until eight had been given. This was repeated on the three succeeding days. In the four days the patient received about 120 gr. of camphor. Recovery followed and the writer evidently believes that the camphor had something to do with it. [L. D. C.]

3. Bachmann maintains that the Riva-Rocci and other methods of estimating blood pressure from the disappearance of the arterial pulsation at some distance from the point of compression are essentially faulty and the results obtained necessarily erroneous. It can be shown, he says, that while the radial pulse has disappeared, there may be a pronounced pulsation in the part of the brachial artery under compression. All such sources of error are removed by the sphygmometric oscillometer recently devised by Pachon. The writer appends a table showing blood-pressure readings obtained with both the Pachon and Riva-Rocci instruments on a large number of individuals of all ages. According to these observations, the systolic pressure estimated by the Riva-Rocci method averages 20 to 40 mm. lower than when estimated with the Pachon instrument. [L. D. C.]

2. Coffey found that, in the direct transplantation of the common bile duct into the intestine, the intestinal pressure caused a very marked and serious dilation of the duct. This he was able to avoid almost wholly by making a physiologic transplantation under the peritoneal and muscular coats of the intestine for about one half to three fourths of an inch before the duct was made to enter the mucous layer. This simulates nature's way or the anatomy of the entrance of the common duct into the intestine. This he also did in implanting ureters into the intestine in dogs and found that the mortality from ascending infections along the ureters from the intestine was practically eliminated by this physiologic method of transplantation.

8. Kahlo emphasizes the neurotic influence in practically all forms of colitis. Mental depression of some degree is a very constant feature. Many of the symptoms may be due to the underlying neurotic element, but most of them, he believes, are the result of auto-intoxication, as they usually disappear as soon as the digestive disturbance is relieved. Gastric disorders are the most common complications of colitis. Treatment should be for the individual and not bound by any set rule. He believes that practically all of that severe type of cases for which appendicostomy and cecostomy are recommended can be cured by medical means and quotes Richardson, who says, "Operations on the neurasthenic return nothing to the patient. Her last state is worse than her first, and is often pitiable. The best rule is to forbid surgery until every medical and palliative measure has proved useless." [E. H. R.]

8. PEMBERTON, R. *A Metabolic Study of Myotonia Atrophica.*
9. *JONES, G. I. *Chronic Influenza and Its Relation to Neuropathy.*

1. Forchheimer considers that the drug treatment of diabetes mellitus has been unduly neglected. On empirical grounds, as illustrated by cases which he reports, he recommends the trial of arsenic (Fowler's solution), of hexamethylenamine, and of belladonna.

2. Foster's article is an extremely useful description of the dietetic treatment of diabetes as applied to the individual patient. Its chief value, however, lies in its attention to details which cannot be abstracted. Comprehensive diet tables are given, and numerous receipts for the preparation of diabetic foods.

3. Stoner has collected with great care the literature of vaccine therapy as applied to a wide range of diseases, both in prophylaxis and in treatment. General infections are first considered, then local infections of the different systems of the body, and also diseases in which the infectious element is not clearly established. From the results he concludes that vaccines should only be employed, first, in general infections after blood cultures have been made and the infecting organism identified; and, second, in local infections in which the organism has been isolated and identified or in which the symptoms are so marked that a mistake in diagnosis is beyond a possibility.

4. Deaver reviews the various theories as to the etiology of malignant disease, but without new conclusions. His article is mainly a plea for early diagnosis, since carcinoma is in its beginning essentially a localised process theoretically susceptible of surgical eradication.

5. Hunt maintains that in addition to the atrophic paralysis of the hand having origin in disease of the spinal cord or of the muscles themselves there should be recognised an atrophic paralysis of *neural* origin. This condition he describes as of two types, the *hypothenar type*, in the distribution of the ulnar nerve, and the *thenar type*, in the distribution of the median nerve. He reports cases in which these nerves have been subject to pressure in the work of the patient; alcoholic excess seems also to have been a factor.

6. Coakley has found that of a series of cases of acute otitis media, 81% had sinus disease, and that of cases of acute sinusitis, 42% had acute otitis media. The likelihood of a causal relation between the two is strengthened by the fact that they were usually found to be on the same side.

7. Dana reports a case of hematoporphyrinuria following apoplexy not to be traced to drugs ingested. From the absence of hematin in the urine he believes the disease to be independent of hemorrhage or hemolysis, — more probably a disorder of metabolism.

9. Jones emphasizes the frequent occurrence of influenza as a chronic infection and its possible rôle as a contributing cause of nervous exhaustion, neuroses and other symptoms. [F. W. P.]

2. Forlanini considers that artificial pneumothorax may actually heal pulmonary tuberculosis and that after the operation the lung expands to its full extent again. The earlier the process and the less extensive, the more successful the full lung expansion, but even after long relaxation the lung will expand to normal again. Thus, if a second lesion should eventually occur in the second lung it would be perfectly proper to make an artificial pneumothorax there also. [C. F., JR.]

15. Rühl, K. *Angelo Mosso.*
16. Neumann, O. P. *Scientific Healing and Its Adversaries.*

1. The writer describes various methods of staining amebæ, and of making permanent smears and sections of suspected material for further study. He thinks that these methods will increase our knowledge of the distribution and varieties of amebæ and urges that they be looked for systematically not only in normal stools in chronic indigestion of patients from the tropics, but also in chronic bone diseases, particularly of the lower jaw, in cervical adenitis, in diseases of the genito-urinary system and in exudate from the pleural cavity and peritoneum. [G. C. S.]

Berliner Klinische Wochenschrift. No. 3.

Jan. 16, 1911.

9. Passow, A. *Otiatrics in Berlin.*

3. The author gives the theoretical grounds for the use of venesection and saline infusion in the treatment of diseases of the skin. He describes the technic in detail. In the report of eight cases he states the amount of blood withdrawn and the amount of salt solution used in each case. The results he has obtained in the treatment, by this method, of cases of pruritus universalis, urticaria, erythema exsudativum multiforme and dermatitis herpetiformis, have been so satisfactory that he feels that this treatment should have wider use. 1. Läwen reviews the work which has been done on extradural anesthesia from 1901, when it was first performed by Cathelin, and points out the errors in technic which have thrown the method into disrepute.

He lays special stress on three points: First, the choosing of a proper anesthetic agent. He used at first novocain chloride, but found that this did not give such uniform results as novocain bicarbonate. Secondly, he points out that, as in intradural anesthesia the patients are sitting up when they are injected, whereas he believes that the head should be lower than the pelvis. Thirdly, he points out that the nerve trunks have a thick, tough connective tissue sheath, which must be penetrated by a solution of the proper concentration.

He then gives a table of eighty operations such as hemorrhoids, fistulæ in ano and operations on the external genitalia where this form of anesthetic has been used by him with almost uniformly good result.

He gives in great detail the formulæ for the proper preparation of both the novocain chloride and the novocain bicarbonate solutions, and thoroughly explains the technic of the injections.

He explains that there are three possibilities by which the injections may cause anesthesia.

(1) By penetrating into the extradural space through the dural sheath.

(2) By filtering through the dura into the cerebrospinal fluid and acting as an ordinary lumbar intradural injection.

(3) By diffusing through the sacral foramen and penetrating the dural sheath to the nerve roots.

Läwen, however, considers that the first method is the correct explanation of the cause of anesthesia.

The remainder of the paper is an analysis of the tabulated operations done by this method. [J. B. S., Jr.]

5. Guinea pigs sensitized to a serum by subcutaneous injection react with anaphylactic symptoms to a fresh injection of the same serum in the spinal canal. If, how-

ever, the fatal dose is given into the spinal canal in small doses it loses its mortal action. These conclusions are some that these authors draw from their observations and experiments. They also find that this fatal dose loses its power when given in small doses, no matter in what manner, whether subcutaneously, intravenously or intraperitoneally, it is introduced. The anti-anaphylactic immunity obtained by the spinal injections lasts only twelve to fifteen days.

6. These authors describe in detail with accompanying photographs three types of parasite which appear in the lower animals' blood in the Congo. One is a trypanosome, the other a small filaria and the third a parasite which appears within the leucocytes. [C. F., JR.]

1. Cuneo continues his studies in the proteid metabolism of certain nervous and psychic affections. His first article (*Bullettino*, 1909, Vol. lxxx, pp. 449–464) dealt with trigeminal neuralgia; the present paper considers manic-depressive psychoses and dementia precox. He believes that the metabolic alterations observed in both classes of conditions do not have as much effect on the morbid process in the latter as in the former. He promises further continuance of his researches. [R. M. G.]

## Obituaries.

### HENRY POWER, M.B.

HENRY POWER, M.B. LOND., F.R.C.S. ENG., who died on Jan. 18 at Whitby, in Yorkshire, England, was one of the most eminent ophthalmologists in Great Britain. He was born at Nantes, in France, on Sept. 3, 1829, the son of a British army officer who had fought in the Peninsula and at Waterloo. On account of his father's frequent changes of residence, the boy obtained his early education at a number of different schools. In 1844, on his deciding to become a physician, he was apprenticed to a Mr. Wheeler, of London, who was afterwards chairman of the Board of Examiners at the Apothecaries' Hall. Subsequently Mr. Power took the medical course at the University of London, from which he graduated in 1855 with a scholarship and gold medal in physiology and comparative anatomy and in surgery. In 1851 he had been appointed demonstrator of anatomy at the Westminster Hospital, where he lectured for ten years. In 1856 he was appointed assistant surgeon to the Royal Westminster Ophthalmic Hospital and in 1857 to the Westminster Hospital. In 1867 he resigned the latter position to become ophthalmic surgeon to St. George's Hospital, and in 1870 was made first ophthalmic surgeon at St. Bartholomew's Hospital.

Mr. Power was a skillful operator, and in addition to his hospital duties had a large and successful private practice. He was interested in many branches of science besides medicine, and was a prolific writer and editor. He was professor of physiology at the Royal Veterinary College from 1881 to 1904; vice-president of the Royal College of Surgeons of England in 1885; and president of the Ophthalmological Society of the United Kingdom from 1890 to 1892. For over forty years he was a member of the editorial board of the *Lancet*. Nor were his activities limited to literary and professional fields. He was an excellent artist in pen and ink and water-colors, and illustrated many of his own publications. That he was a man of indefatigable industry is obvious. It is related of him that for many years he never went to bed till 2 A.M., and always rose at 6 for a walk or bicycle ride before breakfast. His health was excellent till shortly before his death, at the age of eighty-one. He is survived by a large family of children.

His life is of interest, not only as an example of great individual vigor, energy and versatility, but as a type of the finest professional product of English stock and English methods of education in a generation that is now, unhappily, passing away.

### EDWARD HITCHCOCK, M.D.

DR. EDWARD HITCHCOCK, who died on Feb. 15, at Amherst, Mass., was born in that city on May 23, 1828. He graduated from Amherst College in 1849, and in 1853 received the degree of M.D. from the Harvard Medical School. After teaching chemistry and natural history for several years at Williston Seminary, Easthampton, Mass., he went abroad to study comparative anatomy at the British Museum in London. In 1861 he returned to this country to become professor of hygiene and physical education at Amherst College, a position which he held until the time of his death. During this long period he was an enthusiastic advocate of the importance of physical training in the preparation for life, which should be the object of a college education, and was a pioneer in scientific work in this field. A published obituary notice says of him:

> "He was one of the most progressive men in the educational field. While a profound scholar, his activities were not limited to the cloister. He was as deeply concerned for the public welfare as for academic interests."

He was for many years a member of the Massachusetts State Board of Charity and a trustee of Mt. Holyoke College and of Williston Seminary. He was the author of a textbook on "Anatomy, Physiology and Anthropometry," and of numerous papers in his special subject. He is survived by his widow, by three daughters and by four sons.

## EDWARD STRONG BOGERT, M.D.

Dr. Edward Strong Bogert, who died on Feb. 16 in New York City, was born at Geneva, N. Y., on May 7, 1836. After graduating from the Medical Department of the University of the City of New York, he entered the United States Navy as an assistant surgeon on June 10, 1861. He served throughout the Civil War, and on April 6, 1866, was promoted to the rank of surgeon. From 1867 to 1870 he was assigned to the New York Naval Hospital Laboratory. Subsequently he served for four years at the Marine Barracks, Brooklyn, and was then detailed to sea duty on board the *Monongahela*. In 1883 he was made fleet surgeon of the Asiatic squadron, and later was detailed to the Brooklyn Navy Yard. In 1889 he was appointed president of the New York Naval Examining Board, and from 1892 to 1895 was in charge of the Naval Hospital at New York. On May 7, 1898, he was placed on the retired list with the rank of medical director, but during the Spanish War served as recruiting officer at the Charlestown Navy Yard. On June 29, 1906, he was advanced to the rank of rear admiral for services during the Civil War. He was a member of the Medical Society of Alumni of Bellevue Hospital. He is survived by one son, also a surgeon in the navy.

# Miscellany.

## INSTRUCTION OF HOSPITAL CORPS IN THE NAVY.

An order has recently been issued by the Secretary of the United States Navy Department with a view to systematizing and establishing uniformity in the instruction of members of the hospital corps aboard the vessels of the service. The details of this order are of interest as indicating the intended scope of the training in comparison with that given to male nurses in large civil hospitals.

"In order that the instruction of members of the hospital corps afloat may be conducted efficiently and in accordance with a definite and uniform system throughout the service, it is directed that instruction be given on the following subjects and in the following order aboard every ship of the navy to which there are two or more medical officers attached:

"1. Medical and surgical nursing.
"2. Materia medica and practical pharmacy.
"3. Emergency surgery and first aid; application of splints and occlusive dressings.
"4. Bandaging.
"5. Anatomy and physiology.
"6. Transportation methods.
"7. Aseptic operation drill; sterilisation; preparation of patient for operation.
"8. Review.
"9. Medical and surgical nursing.
"10. Materia medica and practical pharmacy.
"11. Emergency surgery and first aid.
"12. Bandaging.
"13. Hygiene; personal and ship hygiene; venereal prophylaxis.
"14. Medical records; care of instruments and medical stores.
"15. Emergency surgery and first aid.
"16. Quiz and general review.

"To attain satisfactory results, instruction shall be given, so far as practicable, on four days of each week, for a one-half hour period on each day, in accordance with the schedule given above, the schedule being repeated beginning with the seventeenth day of such instruction. The course shall be so planned as to be continuous and progressive throughout the cruise. In addition to the course given above, each hospital apprentice, during his day's duty, shall be given an opportunity to learn by practical experience the proper methods of keeping sick-bay records regarding treatment, temperature, diet, etc., the use of proper forms and the methodical tabulation of such data. To this end, hospital apprentices shall be detailed for duty of sick-bay recorder. The medical officer of the ship shall assure himself that the hospital steward is properly qualified to carry out his work as an instructor, and shall take such measures as may be necessary to see that he is thoroughly informed in the duties of his rating."

Such a scheme of instruction, conscientiously carried out, should afford a very thorough and useful education in the duties of the hospital orderly, and might to advantage be imitated by many institutions ashore.

## CONTINUANCE OF THE PLAGUE IN ASIA.

Reports from Asia indicate that the epidemic of bubonic plague, though checked to some extent in southern Manchuria, continues to spread through the northern districts of that country. There are said to be still 250 deaths daily in Harbin. At Shantung 12 physicians and over 1,000 natives have died. At Pu Chia Tien there have been over 1,800 deaths, and at Chefoo, 300. In China, over 1,000 deaths are reported to have occurred within the circuit of the Great Wall, and it is estimated that the epidemic has thus far cost 65,000 lives. The intense cold, which further augments the sufferings of the people, has frozen the ground so hard as to make burial impossible, and the bodies are piled in hundreds awaiting cremation. Despatches from St. Petersburg, on Feb. 17, state that bubonic plague has appeared in Astrakhan, on the coast of the Caspian Sea, and up to Feb. 8 had caused 30 deaths in that province. It is announced that the first meeting of the international medical congress to consider the plague problem will be held at Mukden on April 3. Dr. G. Galeotti, director of the pathological institute of the University of Naples, has been invited by the Chinese government to act as its representative.

## Correspondence.

### TREATMENT OF PHTHISIS BY ANTISEPTIC INHALATION.

BOSTON, Feb. 15, 1911.

*Mr. Editor:* In the issue of the JOURNAL of Feb. 9, page 213, you make editorial comment on the article of Dr. I. Burney Yeo, of London, in the *Lancet* on "Pulmonary Tuberculosis Treated by Continuous Antiseptic Inhalation," stating that "this deserves the attention of the profession." There are constantly appearing isolated cases of pulmonary tuberculosis treated by this method. Dr. Beverly Robinson, of New York, as you state, is the leading exponent of this method in this country. Dr. Lees, of England, and Dr. Maggiorani, of Rome, and others have reported similar cases. A large number of these cases have been at a sanatorium while undergoing this treatment.

Both in this country and in Europe, the inhalation treatment of pulmonary tuberculosis has been tried and found wanting. If it has not been found of value by such authorities as Dr. Trudeau, the late Dr. Janeway, Dr. Miller, Dr. Baldwin, Dr. Vincent Bowditch and innumerable others, I believe it is stretching a point to say that it deserves the attention of the profession; it would seem a great pity if, from the approval of this method by the JOURNAL, any consumptives were given this treatment of somewhat doubtful value at the expense of the known advantages of sanatorium methods.

Very truly yours,

JOHN B. HAWES, 2d, M.D.

[In the issue of the *Lancet* for Jan. 28, on page 262, are communications from Dr. Dundas Grant, of London, and from Dr. C. Muthu, of the Mendip Hills Sanatorium, Wells, both endorsing Dr. Yeo's recommendation of continuous antiseptic inhalation and reporting favorable results from its use. The item in our *Miscellany* was intended for information rather than unqualified approval. Even though antiseptic inhalation have no curative value, there is no proof that it is not a useful palliative agent in conjunction with sanatorium treatment or otherwise. — ED.]

### SOCIETY NOTICES.

THE NORFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting of the society will be held at Masonic Temple, 171 Warren Street, Roxbury, Tuesday, Feb. 28, at 8 o'clock. Business. Communication: "Some Remarks on Sequels of Laparotomies," James A. Riley, M.D. Discussion by E. W. Cushing, M.D.; W. P. Bolles, M.D.; A. N. Broughton, M.D.; J. C. Stedman, M.D. Refreshments after the meeting.

BRADFORD KENT, M.D., *Secretary*,
798 Blue Hill Ave., Dorchester.

THE ESSEX SOUTH DISTRICT MEDICAL SOCIETY. — The fourth meeting of the year was held at the Lynn Historical Society Rooms, Exchange Street, Lynn, on Tuesday evening, Feb. 21, 1911. Dr. William S. Gotthell, Professor of Dermatology at the New York Post-Graduate Medical School, addressed the meeting on "Syphilis in Picture." After this he read a short paper on "The Present Status of the Arseno-Benzol Treatment" (606). The discussion was opened by Drs. Johnson and Bangs of Lynn.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION. — The twenty-fifth annual meeting was held at the Hotel Vendome, on Thursday, Feb. 23, at 3 o'clock. The annual report was presented and officers for the ensuing year elected. Miss Martha H. Stark, superintendent of staff nurses, made a report, and addresses were given by Miss Alice L. Higgins, general secretary, Associated Charities; Dr. Howard T. Swain, senior physician to out-patients, Boston Lying-In Hospital; Mr. M. M. Davis, Jr., director of Boston Dispensary, who spoke on "The District Nurse and the Community."

### RECENT DEATHS.

NICOLA, CHARLES CHESTERFIELD, M.D., M.M.S.S., died at sea, Feb. 6, 1911, aged forty-four years. Residence and office, Attleboro, before death.

DR. THOMAS MARKLEY TREGO, of Albany, N. Y., a descendant of Peter Trego, who came to this country with William Penn, died on Feb. 15. He was born in New York City on Aug. 31, 1847, and was graduated from Rutgers College in 1870 and from the College of Physicians and Surgeons, New York, in 1874. At the time of his death he was physician to the Child's Hospital and other institutions in Albany.

DR. BENJAMIN T. ABBOTT, of Ocean City, N. J., died suddenly on Feb. 17. He was sixty-seven years of age, and was graduated from Jefferson Medical College in 1870.

DR. EDWIN D. LEIDY, of Flemington, N. J., died on Feb. 17. He was fifty-three years of age, and was graduated from Jefferson Medical College in 1885.

DR. CHARLES F. KINGSBURY, who died last week at West Medford, Mass., was born in Gilsum, N. H. He practiced medicine first at Stoddard, N. H., and later at Lyme, N. H. He served for three years as chairman of the New Hampshire State Board of Agriculture. In 1888 he retired from active practice.

DR. THOMAS JAMES MANAHAN, who died on Feb. 14 at Brookline, Mass., was born in Boston in 1873. He received the degree of S.B. from Harvard in 1896, and that of M.D. in 1899. In 1898 he served as first assistant surgeon on board the hospital ship *Bay State* during the Spanish-American War. In 1899 to 1900 he was a surgical house officer at the Massachusetts General Hospital. He is survived by his widow, by two sisters, and by six brothers.

FRANK ORLANDO WEBBER, M.D., M.M.S.S., died of pneumonia, on Feb. 14, at Cambridge, Mass., aged fifty-six years. He was born in that city on March 15, 1855, the son of a physician. After studying for two years in the Massachusetts Institute of Technology, he entered the Harvard Medical School, from which he received the degree of M.D. in 1877. He had practiced medicine in Cambridge from that time until his death. He is survived by his widow and by three brothers.

WILLIAM PALMER CHISHOLM, M.D., M.M.S.S., of Brockton, Mass., died at Taunton, Mass., on Feb. 16, at the age of fifty-seven years. He was born in Nova Scotia, but came to Brockton in 1870. He received his medical degree in 1881 from the University of New York, and for over twenty-five years was a well-known practitioner in Plymouth County. He was a Fellow of The Massachusetts Medical Society, and a member of the Plymouth County Medical Society and of the Brockton Medical Society. He is survived by his widow, by two daughters, and by one son.

DR. AMMON FARNSWORTH DAVENPORT, who died on Feb. 17, at North Adams, Mass., was born in Colerain, Mass., on Oct. 24, 1837, the son of a physician. He studied medicine for a time at the Berkshire Medical College in Pittsfield, Mass., but subsequently went to the Pennsylvania College of Dental Surgery, from which he graduated in 1868. After practicing for several years in New York City, he finally settled at North Adams. He was a member of the American Dental Association and of the Massachusetts State Dental Association, and a member and former president of the Connecticut Valley Dental Association. He is survived by his widow, by one daughter and by one son.

## Symposium.

### STUDIES IN INTESTINAL DISTURBANCES IN INFANTS.

### I. LOOKING BACKWARD.

BY WILLIAM E. FAY, M.D., BOSTON.

THE progressive steps in the care and treatment of infants and young children in the Floating Hospital in the past ten years is of interest in its constantly advancing parallel with the general progress of knowledge in pediatrics and its adaptation to the needs of the community.

Formerly there was a great variety in the maladies for which the little patients were received. The sea air was sought for all.

In cases of extreme infancy and premature cases, their sensitiveness to sudden changes in the weather made protection difficult.

Infants with six months' normal growth behind their illness did far better, and, with those older, responded gratefully to treatment.

The one open-air ward then existing was the favorite place for nearly all, save certain cases of bronchitis and the very young. This experience paved the way for making open-air conditions possible in other wards as now.

Among the subjects of early special study and interest several may be mentioned.

The behavior of frank pneumonia in the open-air ward.

Reduction of fever by open-air exposure under circulatory stimulation by gentle massage.

The relation of edema in infants to causes other than renal and cardiac.

The discarding of tapping the ventricles of the brain in hydrocephalus.

The value of lumbar puncture and knowledge from fluid obtained.

The fortunate use of Flexner's serum.

The careful application of principles of surgical asepsis to prevent contagion between ward beds, some of which were occupied with bowel infections.

With the advance in acquaintance with the flora of the digestive tract, inhibition of fermentation by use of lactic acid bacilli was tried with some apparent confirmation of its value.

The uses and methods of producing better milk became familiar.

The therapeutic aid of vaccine in furunculosis sometimes failed by reason of the low vitality of the cases, apparent success following its use in bladder infection with the colon bacillus.

Tuberculin was used for diagnosis.

In the study of the Shiga bacillus the addition to knowledge did not avail for cure, in an early research made through the aid of the Rockefeller Institute.

Recent demands of the hospital season have centered increasingly upon care of the diarrheal diseases. Always prominent, they now exhaust most of the ward space.

The "cleaning up" of the newly received child, usually having a digestive tract laden with material furnishing food to all toxic conditions, has always been well done and has saved many lives.

To this end castor oil, calomel, salines and lavage have been put to every shade of use.

Intestinal antiseptics empirically tried became practically discarded.

Topical applications in the bowel were bismuth or opium in starch solutions, normal salines, and silver solutions weak, until the past season.

After the first treatment with usually quick improvement there was always one problem pressing. The same problem confronted every case of atrophy, of hereditary enfeeblement, of long-standing illness and of extreme infancy, — the problem of nutrition. Case after case could be brought to partial gain, temporarily holding its own. Then began a decline from lack of native vitality, or lack of ability to provide a food which could be assimilated by organs with diminished or undeveloped function. Infants having vitality remaining after being suspended as it were on sterile water supplied by the mouth, the bowel or through the skin during the period of elimination of toxins, lived. Infants without that inherent vitality were dying. The value of stimulants though recognised proved relatively small. This may be explained by the fatty degeneration of the heart muscle proved by histological examination in some of the cases.

To find or adapt some nutrient which could be accepted at an earlier moment without relapsing the patient was ever the search. Most carefully adapted percentage formulæ, with split proteid, or otherwise, cereal diluents, milk whole, fat-free or pancreatised, albumen solutions, wheys, decoction of tea and buttermilk, all had their successes and failures, mostly failures in the weakest cases.

It was evident that there were no rules of age or weight to accept unless based upon some data which further individualised the condition and need of the case.

The basis for this began to be laid through the systematic study of the infant stools, which interpreted, when understood, what nature might need by what she refused to do. Fuller revelation as to the digestion of fats, and proteids, the presence of pus, blood, and bacteria, belongs to the most recent seasons.

This knowledge with the application of principles of caloric need had little place in the skill and experience of the older times. Now it is supplemented by the excellence of the food laboratory. And there must be unalloyed satisfaction because a dream of the past has been made a fact of the present, namely, the finding of suitable sources and developing a method of transfer by means of trained nurses to provide extreme infancy and extreme weakness with human milk, with which, after all, no substitute can compare.

---

THE promotion of the Kaiser to the honorary title of Doctor by the Prague medical faculty will take place soon in the throne room of the palace in Berlin. The rector of the Prague German University, the present dean of the medical faculty, Professor v. Jaksch and Professor Hering will come to Berlin to officiate. — *Jour. Am. Med. Asso.*

## II. BACILLARY DYSENTERY. ITS BACTERIOLOGY, BIOCHEMISTRY AND THEIR RELATION TO TREATMENT.*

BY ARTHUR I. KENDALL.

(From the Department of Preventive Medicine and Hygiene, Harvard Medical School, and the Boston Floating Hospital.)

THE discovery of the dysentery bacillus by Shiga, in Japan, and the work of Flexner and others in this country, marks a very important epoch in the history, etiology and treatment of dysentery not of amebic origin. The investigations of these workers have shown that a group of closely related organisms, whose morphological and biological characteristics are too well known to repeat here, are causative agents in producing the disease variously known as bacillary dysentery, infectious diarrhea, acute specific dysentery, epidemic diarrhea and other names.

Bacillary dysentery must be regarded as a serious disease, particularly in young children, and it is very desirable, both from the standpoint of the patient and the community, to be able to differentiate sharply between cases of true dysentery, caused by the dysentery bacillus, and cases of severe enterocolitis of unknown etiology, but in which the dysentery bacillus is absent. It is particularly important to make this distinction, since, as Stengel [1] has pointed out, "It is practically impossible to separate cases [of enterocolitis] due to ordinary causes from instances of epidemic diarrhea produced by *B. dysenteriæ* except by bacteriological methods."

Although this paper is not concerned with the clinical picture of bacillary dysentery, it will be necessary to refer briefly to what may be termed the "cardinal symptoms" of this disease as it is seen typically in young children in order to bring out certain facts supporting Stengel's statement that the symptomatic complex is not an infallible guide to the etiology of the disease.

The cardinal symptoms of bacillary dysentery are diarrhea, tenesmus, continued fever and prostration, with blood, mucus and usually pus in the stools.

There are mild cases of diarrhea which are of brief duration which yield more or less readily to treatment, and yet there may be considerable numbers of typical dysentery bacilli in the stools. These cases, not serious from the standpoint of the patient, may be a source of danger to other children, particularly if they be in the same wards, and it is unnecessary to dwell upon the ways and means through which infected material from babies harboring these unsuspected bacilli might be transferred to other babies already weakened by disease, thus spreading the infection.

In the past it has frequently been impossible to isolate dysentery bacilli from all cases which clinically are bacillary dysentery; that is to say, from all cases exhibiting the cardinal symptoms of this disease. This discrepancy has not infrequently amounted to 10 or even 15% of the cases. Investigators have attributed this lack of agreement between the clinical and bacteriological findings to imperfections in bacterial technic, and doubtless in many instances this supposition is correct. In a recent communication (Kendall and Smith) attention was called to the fact that there are cases which are clinically bacillary dysentery, while bacteriological examination has failed to reveal the presence of dysentery bacilli in the stools, or at least it was impossible to recover them in successive trials, while, on the contrary, gas bacilli (*Bact. Welchii*) could be very readily demonstrated. These cases are, therefore, apparently not to be regarded as instances of bacillary dysentery, but rather as belonging to the group of the so-called fermental diarrheas. This supposition is strengthened by the fact that these cases do badly upon the dysentery treatment and respond readily to sour milk therapy.

These points are mentioned to call attention to the fact that the clinical diagnosis should be corroborated by a thorough bacterial examination to insure accurate statistics. On the one hand, cases of diarrhea not presenting the cardinal symptoms may in reality be instances of bacillary dysentery, and, on the other hand, patients presenting a symptom complex indistinguishable from that of bacillary dysentery (particularly in the absence of a good clinical history) may not be cases of bacillary dysentery at all, but of a type of diarrhea in which the gas bacilli are present in relatively large numbers and in which this organism appears to play a prominent rôle.

Medical statistics of bacillary dysentery, therefore, are subject to correction unless they are based upon the findings both of the clinician and the bacteriologist. From the standpoint of the health authorities, the mild, unrecognised cases must be regarded as a problem to be taken into consideration in preventing the spread of the disease.

The dysentery bacilli appear to produce their harmful effects through the elaboration of toxins which recent investigators claim have specific affinities for the anterior horn ganglion cells and the epithelial cells of the intestinal mucosa. The Shiga type of organism produces a powerful extracellular toxin, while the Flexner type belongs to the group of the endotoxins. The poison of the latter appears to be less harmful than the former.

It should be stated that the numbers of dysentery bacilli which can be isolated from the feces of dysentery patients bear no constant relation to the severity of the disease; it is possible to obtain large numbers of typical bacilli from the dejecta of mild cases, and it is equally true that it is often difficult to isolate even a few organisms from the severe cases. Again, certain cases show signs of profound toxemia almost from the start, and die early in spite of the most persistent treatment, while other cases appear to be much less toxic and recover after a more or less protracted illness. It is impossible to predict *a priori* just how the dysenteric toxins will act upon a given patient, although the Shiga infections are more fatal than the Flexner types. The considerable differences in reaction to the toxins

* Read before The Massachusetts Medical Society, Jan. 4, 1911.
[1] Osler's Modern Medicine, v. p. 385.

of the dysentery bacilli should be borne in mind in discussing the efficiency of therapeutic measures, since it appears that certain cases are doomed from the time they are seen by the physician, although they may survive for a few days. It is not possible with our present knowledge to estimate the relative importance respectively of the individual idiosyncracy to the dysenteric toxins, the numbers of bacilli actually present and the virulence of these organisms.

Besides the dysentery bacilli, two other organisms are commonly represented in the intestinal flora of bacillary dysentery, at least as it was seen on the Floating Hospital this last summer, namely, *B. coli* and the *streptococcus*. This is by no means an original discovery; indeed, these organisms have been noted in cases of dysentery in association with the dysentery bacillus ever since the etiology of the disease has been established.

To make clear what is to follow concerning the diet of dysentery patients, it will be necessary to discuss in some detail certain important and hitherto neglected facts concerning the biology of bacteria in general, and of these organisms in particular.

In dysentery cases, particularly in infants and young children, the routine treatment has been to withhold all food for several days. This preliminary starvation, together with the numerous alvine discharges characteristic of dysentery, results in a very thorough cleaning out of the bowel so far as food is concerned. The patient, however, must keep up its vital functions, respiration, heart beat and so on, and the source of energy available for this purpose is, first of all, glycogen which is normally stored up in the liver. This glycogen, so physiologists tell us, is utilized in the body as dextrose, of which it is a polymer. Dextrose is normally present in the blood to the extent of about 0.2%. As soon as the dextrose and the reserve glycogen is used up, or at least reduced to a certain minimal amount, the body must draw upon some other source for the maintenance of the vital functions. The important point to remember in this connection is the fact that the dextrose (and its polymer glycogen) is the immediate source of energy, and while the supply lasts the breakdown of other nitrogenous substances is prevented to a very considerable extent; in other words, dextrose spares body nitrogen. Hence, prolonged starvation of dysentery cases (or other diseases) during the initial treatment of the disease results in the more or less complete disappearance of the sugar, and it is very probable that the loss of this protein-sparing action of dextrose is not without influence upon the well-being of the patient.

This protein-sparing action of sugar in preventing protein metabolism in the animal body is even more marked in the case of the bacteria, although the processes involved appear at first sight to be slightly different, and inasmuch as this fact — that carbohydrate prevents bacterial attack upon protein — is the very foundation upon which the work presented here rests, it will be essential to go into the matter in some detail. A few examples will make the problem clear.

Dr. Theobald Smith, in his admirable studies upon the production of toxin by the diphtheria bacillus, has shown that the amount of toxin produced depends to a very considerable degree upon the presence or absence of sugar in the medium in which the organisms are grown. If there is considerable utilisable sugar present, as much as the organisms can ferment, there will be little or no free toxin produced. The diphtheria bacilli attack the sugar in preference to the protein of the medium and only stop when the acidity formed as the result of their fermentative activities has reached such a degree that they can no longer develop. If there is a lesser amount of sugar present in the medium, so that the sugar is used up before the acidity becomes too great, diphtheria toxin begins to accumulate. This formation of free toxin, however, is minimal until the sugar is practically all fermented.

If, now, the diphtheria bacilli are inoculated into media of precisely the same composition as those mentioned above, except that the sugar be not more than 0.2% (this amount of sugar is added to start the organisms growing well), there will be a decided production of free toxin which reaches its maximum some time after the sugar is quite used up. It would appear from this experiment that the production of toxin and the fermentation of sugar are antagonistic processes at least to the extent that the bacteria attacked the fermentable sugar before breaking down the protein constituents of the media, although both are simultaneously present. In other words, *fermentation* (or the metabolism of sugars) *takes precedence over putrefaction* or toxin production (the break down of protein by bacterial activity).

When we remember that the bacterial toxins are produced, so far as we know at present, by the breakdown of protein substances by bacteria, the significance of the presence of carbohydrate becomes apparent. The bacteria utilise the carbohydrate in preference to the protein, and just so long as the carbohydrate is not used up, just so long will the protein be shielded from any considerable bacterial attack. It follows, therefore, that inasmuch as the toxins we have mentioned are the results of protein metabolism by bacterial agency, they will not be formed to any extent in the presence of carbohydrate which can be utilised by the the bacteria.

Dr. Smith tells me that the same principle holds for the tetanus bacillus; the production of toxin depends upon the action of the tetanus bacilli upon protein, and that this action does not take place to any extent until the carbohydrate of the medium is metabolised.

It is a fact that both in the case of the diphtheria and tetanus bacilli the production of powerful extracellular toxins is the salient feature of their importance to medicine, and it is equally true that, with one or two exceptions, the majority of bacteria known at the present time do not produce powerful poisons. It will now be necessary to discuss the influence of carbohydrate

and protein upon the metabolism of organisms not belonging to the toxin-producing class.

Before doing this, however, it will be well worth while to recapitulate what has been said in the last few paragraphs.

It was shown that bacteria acting respectively upon carbohydrate and protein produce from the former fermentative products and from the latter putrefactive substances. The fermentative process takes precedence over the putrefactive if both carbohydrate and protein are simultaneously present in the medium in which the bacteria are growing. The carbohydrate, in other words, is attacked and must be used up before the protein is acted upon to any extent, and in this sense the carbohydrate shields or spares the protein in a similar manner to that obtaining in the animal body where carbohydrate shields protein from metabolism. The products of protein putrefaction were seen to be strongly toxic in the cases of the diphtheria and tetanus bacilli; hence the addition of utilizable sugar to a protein medium suited for the development of these bacteria would be indicated if one wished to prevent or inhibit toxin production.

Turning now to a well-known organism of the intestinal tract which does not produce an extracellular toxin, *B. coli*, we will see if it also obeys the same general rule — utilising carbohydrate in preference to protein. The protocols of an actual experiment will illustrate the case exactly.

Two portions of regular nutrient bouillon, of precisely the same composition and reaction, with the exception that one contained 1% of dextrose, were inoculated with the same strain of *B. coli* and incubated at body temperature for about ten days, then examined bacteriologically and chemically. Bacteriological examination revealed the fact that the cultures were pure and contained no organisms other than the ones inoculated. Chemically, the results were very striking.

That portion of bouillon containing the dextrose had an agreeable odor, a decidedly acid reaction and contained, besides $CO_2$ and $H_2$, considerable amounts of lactic, acetic and succinic acids. No products of protein breakdown could be found, and the whole process was one of fermentation. The protein, with the exception of minimal amounts necessary to meet the nitrogen requirements of the bacteria, was apparently intact. This was, therefore, a typical fermentation.

The portion of bouillon containing the same amount and kind of protein as the first portion but without the dextrose was foul smelling and strongly alkaline in reaction. $NH_3$ and $H_2S$ were freely formed, and, in addition, the medium contained relatively large amounts of typical putrefactive products — indol, some skatol, aromatic oxy-acids and basic bodies. In this case, the protein was attacked and broken down by the colon bacilli and a perfectly typical putrefaction resulted.

It will be remembered that the fundamental conditions obtaining in these experiments were the same as those with the diphtheria and tetanus bacilli respectively. In one set of media sugar was present, and in a corresponding set the sugar was omitted. In all the cases cited, the same sparing or protective action of the carbohydrate for protein was noticed when sugar was present, and in those instances where the sugar was omitted the protein was vigorously attacked.

Recent investigations have shown that the toxin produced by the Shiga type of the dysentery bacillus is produced only in bouillon having a strongly alkaline reaction.[3]

This statement becomes significant when we remember that the reaction of pure fermentations is acid, while alkaline reactions occur in putrefactions, that is, where bacteria act in the absence of sugar on protein.

Further evidence of the generality of this law of fermentation taking precedence over putrefaction is not wanting. At first sight it might appear to be quite foreign to the subject in question to quote certain experiments made by Heilner. Heilner studied the effects of injecting certain sugars into experimental animals and he found that the sugar solutions do not become infected, or, more accurately, that the animals into which the sugars were injected did not develop abscesses at the site of inoculation. It is well-known that protein injections similarly made not infrequently do become infected. Even allowing for the difference in rate of absorption of the sugar and protein respectively, one cannot but be impressed with the remarkable difference in behavior between the two classes of substances, and that the explanation, in part at least, is associated with the innocuous products formed from the metabolism of sugars as compared with the more or less toxic substances derived from bacterial decomposition of proteins. The writer believes that the putrefactive products formed from infected protein injections are of real value to the invading organisms, assisting in their fight to gain and maintain a foothold in the animal body, while the relatively benign fermentative products are of little value to the invading organisms under similar conditions. Many other illustrations also of an apparently unrelated nature might be cited in which the explanation in reality appears to depend upon the same phenomenon, but enough has been said to illustrate the fundamental principles which are taken advantage of in combatting the dysentery bacilli in the human host, namely, that bacteria can, generally speaking, act upon certain sugars (the kinds of sugar vary with different kinds of bacteria) and upon certain kinds of protein, and also that in the presence of both utilisable sugar and utilisable protein, fermentation takes precedence over putrefaction. Inasmuch as the putrefaction products, not the fermentative products, are the harmful substances, it follows that in order to prevent the formation of harmful (toxic) substances by bacterial action, one should

[3] Kolle und Hetsch: "Die Giftbildung im Bouillon erfolgt nur bei stark alkalischer Reaktion des Substrates." p. 250.

produce conditions favorable for fermentation, namely, to present the organisms with utilizable carbohydrate.

Returning now to the associated flora of bacillary dysentery, it was stated that these three organisms are commonly present: the dysentery bacillus (Flexner and Shiga types, or both), *B. coli* and the streptococcus. It was also stated that there is little or no food in the alimentary canal, other than the intestinal secretions, because the repeated evacuations have cleaned the tract out. The residual bacteria are living chiefly upon the intestinal secretions, and possibly the mucus, since food is withheld from the patient. The available sugar is exhausted, and the organisms are forced to derive their nutriment chiefly from albuminous substances. It was shown that bacteria acting upon protein (nitrogenous substances) in the absence of fermentable carbohydrate form putrefactive products, some of which may be very toxic. It must be evident, then, that the dysenteric flora, under the conditions outlined, is essentially putrefactive in character. The dysentery bacilli are forming toxins, which are extracellular in the case of the Shiga type, intracellular in the Flexner variety, and *B. coli* is producing substances such as indol, skatol and aromatic bodies. These latter products are, according to authentic observations, absorbed in part at least from the alimentary canal, paired in the liver and excreted through the kidneys. The patient, therefore, in receiving no food, is being poisoned by the bacterial products elaborated in the intestinal tract, and attempting to detoxicate and excrete these substances in addition to maintaining the normal vital functions of respiration, heart beat and so on.

Realizing these conditions, the writer has proposed feeding such patients from the start with carbohydrate. The principle involved is a twofold one: to furnish an easily assimilable and readily fermentable carbohydrate to change the character of the bacterial activity in the alimentary canal from the proteolytic to the fermentative type, and to furnish nourishment to the patient.

Changing the metabolism of the dysentery and colon bacilli is an important procedure, since these organisms, in utilizing sugar, are not acting upon protein. The result is that the toxin formation by those dysentery bacilli developing in the lumen of the intestines is inhibited, since the organisms become fermentative, while the colon bacilli and the streptococci form lactic and other acids instead of putrefactive products. These latter organisms, *B. coli* and the streptococcus, become antagonists of the dysentery bacilli, since the dysentery bacilli are sensitive to even relatively small amounts of acid, while, coincidently, the dysentery bacillus itself tends to become a harmless acid-forming organism in place of being a toxin-producing bacillus. This leaves the host relatively free to combat the toxin already absorbed, but reduces or prevents further insult in this direction. This procedure, then, is theoretically logical, and experience has shown that it is practically possible.

The patient is benefited in two ways: by a diminished absorption of products of protein decomposition, and by the ingestion of a readily assimilable food. The sugar employed for this purpose was lactose. At first sight it might appear that almost any sugar would be equally efficient, but experience has shown that lactose is a most easily assimilated sugar, and it is, of course, the normal sugar for babies. Furthermore, the flora developing on this sugar is particularly favorable for the patient, which is not the case with certain other sugars.

Lactose is easily and simply broken down in the alimentary canal into dextrose and galactose, and the absorption of these simple sugars is accomplished with a minimal expenditure of energy. It is worth while to contrast this very simple hydrolytic cleavage with the extremely complicated series of events attending the digestion and assimilation of protein, particularly in those cases in which the digestion is seriously upset. The difference in expenditure of energy necessary and sufficient to digest a protein and a carbohydrate such as lactose must be a factor of importance in dangerously sick patients, whose strength is already largely used up.

It has been claimed that the dysentery bacilli penetrate the intestinal mucosa, and may go as far as the mesenteric lymph nodes, and at first sight it would seem that these organisms might be beyond the reach of carbohydrate. Doubtless this is so to a considerable degree. If, however, the attempt be made to restore to normal the dextrose of the blood, it is not inconceivable that the invading bacilli even in the tissues may be reached, and with this idea in mind the expedient of infusing dextrose was tried. The sugar employed for this purpose must be absolutely chemically pure, and Kahlbaum's seems to be the only brand available for this purpose. In addition, then, to the sugar that is penetrating the intestinal mucosa as the result of feeding lactose, it is possible to add to the tissues of the body another portion of sugar through the medium of the blood stream, into which the sugar is absorbed after the infusion.

The amount of dextrose to be infused is easily calculated: a 10% solution of dextrose is isotonic with the blood, and the blood is approximately one thirteenth the weight of the body. Normally there is about 0.2% of dextrose in the blood.

It might be asked: Why not feed dextrose, or maltose, which is a condensation of two molecules of dextrose? The lactose is preferable partly because it is the normal sugar of animals and man, but chiefly because but few organisms except those normal to the intestinal tract can utilise it before it is broken down by hydrolysis. Certain well-known bacteria, for example, *B. acidophilus*, develop rapidly in dextrose, less so in lactose; while these acidoduric bacteria are desirable in small numbers, it would be unwise to encourage their unrestrained growth in the

intestinal tracts of patients fed largely upon sugar for some time for fear of causing excoriations which would almost certainly occur in consequence of the large amounts of lactic acid which these organisms generate. Again, as the writer has pointed out before, there is greater danger of arousing a condition of sugar intolerance if the acidoduric bacteria gain the upper hand.

The procedure outlined above is directed toward the bacteria themselves, and its purpose is to *prevent the formation* of toxic substances rather than to attempt to neutralize them after they have been absorbed by the host. Taking advantage of the fact that bacteria will not attack protein in the presence of easily fermentable sugar, lactose is intentionally fed to the host in order that the bacteria which he harbors will produce acids instead of toxins and putrefactive substances. This lactose also furnishes a readily assimilable food for the host.

While it is not possible to present the full bacterial protocols pertaining to this work at this meeting (they will appear in detail in another communication), they may be summarized in a few words. The characteristic flora of bacillary dysentery, as seen in Boston during the last summer, consists of three organisms, essentially: *B. dysenteriæ* (Flexner, Shiga or both types), *B. coli* and the streptococcus. Under the influence of a lactose diet, the streptococci tend to disappear, a point of the greatest importance, since these organisms frequently cause death in these cases as a terminal infection. The colon bacilli become reduced in numbers and fermentative in place of putrefactive. The dysentery bacilli also tend to disappear. After a few days, longer in some cases, shorter in others, the character of the intestinal flora undergoes a profound change. Gradually Gram-positive bacteria, similar culturally and morphologically to those characteristic of the dejections of normal nurslings, appear in the stools, while the Gram-negative bacilli (dysentery bacilli and colon bacilli) diminish in numbers.

It is interesting to note that this change in the fecal flora, while frequently an indication of recovery, is not always so. The latter cases, which terminate fatally as a rule, appear to be those in which the patient succumbs to the toxemia, as mentioned above. These patients appear to be doomed from the start. It is also possible, as was shown by the summer's experience, to bring about this unfavorable retrogression in the type of the fecal flora by the use of certain foods after the acute symptoms have apparently abated. Very frequently one notices in such cases during the last day or two of life a rather abrupt return of the Gram-negative bacteria, streptococci, *B. coli* and *B. dysenteriæ* associated with a retrogression of the Gram-positive normal intestinal bacteria.

It is very probable that the principles outlined above could be successfully utilized in other bacterial infections of the intestinal tract, particularly in typhoid fever. Typhoid fever is usually a disease of individuals older than those studied in the series of experiments recorded here, and the diet could, consequently, be more varied. With, however, certain modifications which readily suggest themselves, the use of lactose in this disease should theoretically prove helpful.

In Bright's disease, as is well known, milk or buttermilk is strongly advocated in many instances. So far as the writer is aware, this treatment is largely empirical, but it is very possible that in certain cases at least the beneficial results which have been attained are to a certain degree explainable on the basis of the facts outlined above. The character of the food (milk) is such as to encourage a fermentative flora in place of a proteolytic flora. The fermentative organisms would develop rapidly and tend to replace the putrefactive organisms which might be present. In addition, the putrefactive bacteria would tend to become fermentative in their metabolism as well. The natural result would be a saving to the host in the following manner: The liver and kidneys would not have respectively to detoxicate and to excrete the putrefactive products which previously were probably present. If one or both of these organs were weakened, this saving would mean a great deal in the course of the disease. This statement is not to be taken to mean that the cause, either directly or indirectly, of Bright's disease is the excretion of putrefactive products, but merely to call attention to the fact that it is possible that the diet frequently employed in these cases is such as to protect these organs from extra work in detoxicating and excreting putrefactive products.

Certain drawbacks might be predicted for this method of feeding dysentery patients, and they naturally group themselves under three heads: glycosuria, intolerance of sugar and excoriations.

Of the thirty or more cases studied, and in which lactose was administered, little or no intolerance was noticed. Indeed, the use of lactose actually made it possible to administer considerable amounts of fluid without resorting to saline infusions.

With the exception of two cases, glycosuria was not detected. In these instances, it appears that the excess of sugar was eliminated through the kidneys, when the condition promptly ceased.

Severe excoriations did not occur, and only in one or two cases was it possible to demonstrate slight reddening of the buttocks. The babies in which this reddening occurred had been on a pure lactose diet for more than two weeks before the symptoms appeared, and they did not progress to real excoriations. There were no signs of discomfort.

These facts are interesting and noteworthy. One would expect *à priori* to see at least moderate symptoms following the continued use of such a monotonous diet; it may be stated that the lactose, even when fed alone for many days, did not cause any demonstrable harm.

It must be apparent that the procedure outlined above is by no means intended to be a

complete treatment in itself. It is to be regarded, however, as an important initial factor in combatting the disease and in assisting the patient to keep in check the development of a harmful flora, while the clinician administers an appropriate supportive treatment.

In one respect, this work is incomplete. After feeding lactose during the early days of the attack, the problem is, What to feed next? It may be stated that while the writer is not prepared to make any definite statements regarding the after feeding of bacillary dysentery, the use of cow's milk, either diluted or skimmed, is distinctly harmful unless its lactose content is considerably increased. This agrees with the observations of many other observers. Milk, even after convalescence is well established, should be used with the greatest caution.

From purely theoretical considerations, whey or certain cereals would appear to be the most satisfactory foods to give after the lactose, since in these products there is a relatively small amount of nitrogen and an excess of carbohydrate. This excess of carbohydrate is essential to protect the nitrogen from bacterial attack and thus precipitate another relapse.

In any event, it is desirable to give the patient a small amount of nitrogen, which is easily assimilable, as soon as possible, but further increments of nitrogen should be added to the diet with the greatest caution.

This idea of changing the metabolism of invading pathogenic bacteria is, so far as the writer is aware, a new one and hitherto untried for this purpose.

The use of lactose is, of course, not new; indeed, it would be difficult to find any common foodstuff which has not at one time or another been tried in various ways. The writer believes, however, that the early employment of lactose for a definite purpose is novel.

In common with all new procedures and methods, some time must elapse and many trials must be made before the most advantageous use of it can be brought out. Without doubt, experience will indicate improvements and additions which can be advantageously introduced, but the fundamental principles underlying this work appear to be sound, bacterially, and it remains to utilize them to the fullest possible degree.

To summarize:

1. The patient is first given a dose of castor oil or other cathartic to clean out the intestinal tract thoroughly.

2. All food except sterile water is withheld for twelve to fifteen hours to facilitate this cleaning out.

3. Lactose, 5% solution in sterile water, is then fed by mouth for several days, until the acute symptoms abate, or until it becomes apparent that the patient requires some nitrogenous food.

4. Whatever nitrogenous food is selected must be fed cautiously, in small amounts, simultaneously with an excess of utilizable carbohydrate to protect it from bacterial attack.

5. The lactose should be fed in rather small amounts, often repeated to keep up a stream of this sugar in the alimentary canal, otherwise the proteolytes will be able to attack whatever nitrogenous substances may be present in the alimentary canal between the doses of lactose.

6. Dextrose (Kahlbaum's) may be infused, preferably as a 2.5% solution in physiological salt solution to bring to normal the dextrose content of the blood and to furnish fluid to the patient.

7. This feeding of lactose is intended to accomplish a twofold purpose: to furnish to the host a readily assimilable food, requiring a minimal expenditure of energy to metabolize it, and to change the character of the metabolism of the dysenteric flora from the proteolytic to the fermentative type. This change in the type of the intestinal flora is particularly desirable to prevent further intoxication of the host and to give him a better chance to combat the poisons already absorbed.

Upon looking over the summer's work it is apparent that certain mistakes were made, and while these mistakes are deplored, they are not wholly in vain, since they furnish the most reliable method for determining the efficiency of this method of procedure. Of these errors, two stand out prominently:

1. Dextrose was not used soon enough in the majority of cases. Dextrose infusions should be given at the very start, while the patient is undergoing the initial starvation. By so doing the patient is provided with a most readily utilizable food which spares body nitrogen without the slightest expenditure of digestive energy.

2. Lactose also should be fed within twenty-four hours, and if possible within eighteen hours. The longer the carbohydrate is withheld, the longer the dysentery bacilli have a free field to produce toxins.

Finally, in discussing the efficiency of these sugars, two facts should be borne in mind. Lactose (and dextrose) is not in itself a complete treatment, and cannot of itself be expected to save the lives of patients. It is intended to prevent, as far as possible, the production of bacterial toxins in the intestinal tract, to encourage the growth of a more favorable intestinal flora which shall be antagonistic to the putrefactive dysenteric flora, and to furnish a readily assimilable food for the patient during the acute stages of the disease.

If the patient is already overwhelmed with toxins, lactose or any other substance except a specific antitoxin or serum cannot be expected to save the case.

Again, it is perfectly apparent that lactose, or any carbohydrate, cannot be fed for too long an interval without harmful effects, although these harmful effects will, in the majority of cases, be of less consequence than the withholding of all food, or the feeding of purely nitrogenous foods. The after-feeding will determine the fate of the patient in most instances, and this after-feeding, in virtue of the favorable start made by

the lactose, should carry the patient to recovery in the majority of cases.

In conclusion, the writer desires to express his indebtedness to the management of the Boston Floating Hospital staff, the visiting staff, the house officers and the nurses who have co-operated with him in this work.

This work was carried on with funds raised by Dr. Henry I. Bowditch.

## III. INFECTIOUS DIARRHEA. ITS TREATMENT WITH ESPECIAL REFERENCE TO THE BIOCHEMICAL AND BACTERIOLOGICAL STANDPOINT.

BY HENRY BOWDITCH, M.D., BOSTON.

INFECTIOUS diarrhea, i. e., bacillary dysentery, is a menace to all young life and needs all the help we can give in attempting the solution of its prevention and diagnosis and improving its inadequate treatment. A general paper on this type of intestinal infection is not my aim in this communication. A résumé, however, of the clinical aspect of infectious diarrhea will not be out of order to establish at the outset as clear a mental picture of the disease as is possible.

We are dealing with a specific disease which usually appears in infancy and early childhood. It belongs to the general group of dysenteries and depends on bacterial infection of the intestinal mucous membrane and invasion of toxins with their accompanying nervous phenomena. Attacking as it does the ileum and lower bowel, this disease produces pathological inflammatory changes which post-mortem appear as thickened, congested, ulcerated and pseudo-membranous conditions.

Intestinal irritation with its subsequent increase of peristalsis appears early in the disease and gives us usually a typical clinical history and actual appearance of bloody, dysenteric movements. The dehydration of the system through diarrhea, the irritable conditions of the stomach as shown by vomiting, together with the pain subsequent to peristalsis and tenesmus, and the increased hypersensitiveness of the central nervous system, induced by toxemia, all make a disease rightly to be feared during the warm summer months.

### ETIOLOGY.

*Primary factors.* — The all-important etiological factor has been known for a number of years to be dependent on a specific organism. Shiga in Japan, Strong, Flexner and Hiss have clearly demonstrated this disease to be dependent on a bacterial group. The group of organisms varies apparently according to seasons and countries largely. The bacillus dysenteriæ of Shiga is rarely found among infants outside of eastern countries, while the predominating bacteria in the movements with us are those described by Flexner.

The presence of these organisms has been seen in breast-fed and bottle-fed children, varying in effect from a mild form of indigestion to severe forms of ileocolitis. The finding of such bacteria does not necessarily lead to a clinical diagnosis of infectious diarrhea or bacillary dysentery, but should give us a possible means of preventing the spread of this sickness through carriers.

*Exciting factors.* — While predominant during the summer months, infectious diarrhea does occur at other seasons. Important among such exciting factors are bad hygenic conditions. Such cases are far more numerous among the poor of crowded districts in which filth and lack of air and sunlight prevail. The nutrition of children, while playing a part in the morbidity of this disease, plays more of a part in its mortality. Good nourishment does not necessarily protect a child; it merely gives the patient more resistance against the infection.

Previous illnesses, we know from experience, play a not unimportant part; among these are general debilitating diseases, measles, whooping cough, etc., so frequent in early life. Far more important are digestion upsets. The more direct exciting causes are found in the foods, climate and weather.

The effect of climate is most marked in low humid countries where rapid changes in temperature and humidity predominate. These climatic conditions naturally affect all animal life, the child and its food. It lowers the resistance of the former and increases the destructibility of the latter.

*Symptomatology.* — From the intestinal infection and toxic nature of this disease a fairly characteristic clinical picture usually presents itself. The onset of intestinal disturbance is not usually sudden, but may extend over a period of a few days. When sudden in appearance, all other symptoms are correspondingly increased. There is moderate fever, on the average of 101. The pulse and respiration are not much accelerated unless the patient is overwhelmed. The child's mental condition is often bright. There may or may not have been vomiting. The child frequently does not look sick, and the abdomen may show no signs of tenderness or other abnormality. The temperature varies in its height and duration according to the infection and other complications.

The central nervous system is usually dulled. Apathy appears, while restlessness and fretfulness are seen in the severe cases. Convulsions rarely occur, but signs of meningeal irritation, twitchings, spasms, retraction of the neck, etc., are found. The facies are those of prostration (sunken eyes, half closed lids and dry lips). The heart action is usually regular, unless the patient is profoundly sick, when irregularities as to rhythm and qualities of sound are apt to appear. The abdomen, under normal conditions full and not sensitive, is found retracted and tender and usually dull upon percussion. The extremities, which normally are warm and of good color, in profound cases become cold and cyanotic. The reflexes are naturally retarded and hard to obtain in severe cases.

The movements are frequent, may be small or large, peculiarly acrid in odor, liquid, and always contain mucus and blood and pus in greater or less degree. The amount of pus or blood is no true guide to the severity of infection nor to the intestinal pathological changes. Tenesmus is a frequent and distressing symptom.

The *diagnosis* of bacillary dysentery is usually easy. In the majority of cases the movements are characteristic, and the patients present more or less typical pictures. The presence of the dysenteric organism, proven by bacterial examination, is, however, the only absolute means of settling the question, as blood not infrequently is seen in what are known as fermental diarrhea, whereas dysenteric organisms can be demonstrated in cases of apparent mild indigestion. The agglutination reaction of serum is not constant during the early days, while leucocytosis does not exist except in complicated cases.

*Course.* — The course of the disease depends primarily on the virulence of the infecting organism, the resistance of the patient, climatic condition, and proper treatment. Being a more or less acute infection, radical measures are indicated. Its course is short, usually about one week. Subsequent complications dependent on intestinal, circulatory and nervous disturbances prolong the convalescence usually several weeks.

*The prognosis*, judging from reports in various centers, differs considerably. As a rule, 25% to 35% of cases are fatal under the present known forms of treatment during hot weather. Considering the age of the patient usually attacked, and the virulence of the affecting bacteria, and that the vital organ of digestion is invaded, the prognosis must necessarily be very guarded.

*Treatment.* — With the diagnosis of this disease established, its treatment becomes the all-important and interesting problem. In view of the fact that even under the best hands a serum or vaccine for this disease has not yet been found, treatment must still remain largely symptomatic. Up to the present we have carried it on in a more or less empirical manner.

Recent bacteriological studies of the biology and chemistry of intestinal flora through such work as that of Kendall led to our changing the treatment on the Floating Hospital last summer. To the results of our experience, as a preliminary report only, I wish to devote most of my time.

After the initial laxative all agree upon the plan of a temporary withdrawal of foods. The idea apparently underlying this is that after cleaning the intestinal tract, we attempt to starve the bacteria and at the same time give the digestion a chance to recover. Food is generally withheld for a period of from two to ten days, while water is forced by ingestion and hypodermoclysis, for the organism can exist temporarily without food, but needs water on account of the fluids of the tissues being drained from diarrhea and vomiting. Through Flexner's work, dysenteric organisms were found to live on mucous and intestinal secretions, one or both, and thus might become parasites to the patient in spite of entire absence of food. At the same time other organisms, especially the colon group, are found to multiply tremendously. Theoretically and experimentally, these organisms (the colon group) in the presence of sugar have been found to prevent putrefactive products and decomposition.

These bacterial evidences led to the conception of a very early administration of sugar. In the first place, such treatment would alter the bacterial flora; would furnish, in the second place, a form of food that does not putrify and is most easily assimilable by an already impaired digestion.

The following report of the treatment is offered as clinical evidence of bacteriological and biological study of the movements of certain children in the wards of the Boston Floating Hospital during the summer of 1910. This report comprises 39 cases of children from three to sixteen months of age. They were not taken "*in serium*," but were chosen where some hope of life and chance for study existed. Of these, practically 50% died (19). The duration of disease on admission varied from one to sixty days (an average of twelve) in the fatal cases; of those who recovered, from one to twenty-eight days (an average of eight days). For sake of comparison I shall contrast the two groups, those who recovered and those who died.

Treatment divided itself into: I. The initial attack on the specific organisms and their resultant symptoms. II. The treatment of supplementary symptoms and supportive treatment.

I. INITIAL ATTACK ON THE SPECIFIC ORGANISMS.

*Catharsis.* — From the general character of this disease attacking the digestive apparatus, the first important treatment is to purge the digestive tract and theoretically rid the patient of infecting organisms and their products. Naturally this should follow immediately on the first signs of increased peristalsis and indigestion. Medicines used as laxatives are practically limited to three, — castor oil, calomel and sodium sulphate. Castor oil is the one in general use. It is usually well borne and is contra-indicated where vomiting exists. It is given in doses of from two to four teaspoons. Calomel is administered in divided doses of 1-10 gr. until 1 gr. is given. Sodium sulphate is given in various clinics with apparently good results where nausea and vomiting are complications. Prostration and general poor condition almost never contra-indicate initial cathartic. Of our cases all received castor oil, the majority ½ oz. In no case was there any untoward condition noticed.

*Local gastro-intestinal treatment.* — In view of intestinal infection, peristalsis should not be stopped, being the natural effort of the organism to rid itself of the irritating poisonous substances. Local colonic irrigations help this effort in soothing the mucous membrane and mechanically removing the intestinal contents. Nausea and vomiting, the other distressing symptoms, are treated best by bland liquids, lavage and drugs, according to the individual case. Local gastro-intestinal treatment divides its colonic treatment into

irrigations and rectal enemas. Colonic irrigations are contra-indicated only where profound prostration exists. They should be carefully attempted and should be stopped when resultant shock occurs or insufficient return of mucus or blood appears in the water.

*Irrigations* vary according to the material used. The usual solution is *normal saline* (one teaspoon of salt to a pint of water is a good substitute). Stimulating irrigations are given with the addition of silver nitrate 1 to 3% and rarely tannic acid. Previously not more than two irrigations a day have been considered wise. More frequent use is justly criticised as being of little avail in the presence of the frequent movements, and usually adds irritation and loss of strength to the patient. The quantity should never be less than 2 quarts. Clear return washings are the desired result. The temperature varies according to the desired effect — cool irrigations below 98° for elevated temperatures and 102° for subnormal temperatures.

Of the cases under consideration, 18 out of 20 of those discharged well received irrigations. Twelve had one and 6 received two a day for the first two weeks of their stay. Eight were prostrated, with marked temperatures above 101. Of the 19 children discharged dead, 13 received salines not more than once a day. Six received none, being too prostrated. All were seriously sick, with temperatures ranging from 102 to 103. The movements were not increased in number, nor was trauma apparent with increase of blood or pus. Slight to moderate prolapse of the rectum not infrequently occurred, which responded to careful manipulations and painstaking irrigations.

*Silver nitrate* irrigations were administered to 11 of those discharged well and 5 of those discharged dead. They varied in number from one to four during the first two weeks. A 2% to 3% solution was used, the total quantity being one pint and was preceded by a cleansing enema. Repeated irrigations were given in five instances, allowing two to four days' intervals. Three only of the 16 so treated showed any noticeable improvement. These were among the children who were treated with more than two irrigations. The value of such treatment is of doubt. An occasional case apparently seems to do well. What kind of case, strength of solution, proper interval between treatment are questions to be dealt with in an especial investigation.

*Lactose* and *dextrose* were added to irrigations and were also used in enemas for the first time during the season of 1910. Theoretically such treatment might help in changing the flora of the intestine and possibly prevent putrefaction. Absorption of such it was thought might give some nourishment. Lactose was added to the saline solution from 2 to 5% and dextrose from 2% to 4%. In all, 10 received lactose irrigations. While the large majority (8) were of those that recovered, no distinct benefit was manifest nor untoward effect noticed in a general way or in a local intestinal manner. Fifteen cases out of 39 received dextrose enemas for an average of eight days. On comparing those receiving dextrose and those who did not, it can be said that the days of rectal treatment were diminished by an average of four. No intestinal disturbance was perceived nor any marked improvement in the movements seen. Prostrated cases were not upset by this treatment. The retention of such enemas, always difficult at this age, was fairly good in the majority of cases. Sugar was at no time demonstrable in the urine. Such new intestinal supportive and bacterio-chemical treatment, it seems fair to state, added no positive form of helpful treatment. Our cases are too few and the treatment too new to arrive at definite conclusions. Further work may give us more hopeful results.

*Lavage.* — This procedure, while indicated in those nauseated and vomiting, was rarely practiced. Such symptoms seemed to respond to the simple means of gastric sedatives.

*Alimentation.* — Following catharsis and local rectal treatment comes this all-important question of liquids and nourishment by mouth. Temporary abstinence from all nutrition is imperative. This period lasts theoretically until the infection has subsided, temperature has fallen and the nervous irritability of the gastro-intestinal tract has improved. Experience alone can tell whether or no the digestion is ready for food. The longest period of abstinence from milk has been about two weeks. During this time ingestion of water is necessary to keep the fluids of the body and blood as normal as possible. *Boiled water* amounting to the quantity of food usually ingested is given by mouth. This at times must be forced by spoon, medicine-dropper or esophageal tube. The use of such measures should be guided by the condition of the child. From 24 to 32 os. are found to be the average necessity. Boiled water alone is generally not well taken, which is more true in prostrated children, especially when given by bottle. Where small amounts are given, infusions are of some assistance in keeping up the total twenty-four-hour amount. Food when first given is in the form of lactose added to the water. With us in previous years this form of food has been given, on an average, at the end of five days. Cereal waters and jellies have been added which are gradually replaced, according to the case, by digestible forms of milk and milk products (whey, buttermilk, fat-free milk, whole milk and cream whey mixtures). Lime water and alkalies have been added according to the digestion. (Twenty per cent of the milk and cream to allow partial digestion and 50% to exclude gastric digestion.) The length of time for administration of any food or its increase has never, and probably never will be, settled. Where rapid changes have occurred, digestion invariably has become upset. The choice of various milks and their products has been hard. Experience with the character of the movements and general condition have been the main guides.

Bacteriological examination of the movements at intervals may in the future give us some help. Theoretically, the infecting organisms of dysentery and their associated colon groups were thought

to be affected by the administration of lactose, which could form, through the action of the coli organisms, an acid media detrimental to the growth of the Flexner and Shiga bacteria and fight putrefaction. This was found to be the truth. The dysenteric organisms lost their staining properties and disappeared rapidly, while the general bacterial flora was consistently improved.

Of the 39 children herein reported, all received sterile water for not more than three days (an average of two), in contrast to the usual prolonged starvation. After this short interval they received 5% lactose. Of the 20 discharged well and the 19 who died, 14 and 10 respectively (58%) received lactose up to 5% for an average of eight days. Seven of these died during this treatment. The temperatures fell in 17 and remained stationary or increased in 7. The movements diminished in 13 and increased in 11. Blood was increased in 17 and diminished in 5. Of those who recovered, an average of 24 oz. of sterile water was well taken, while barely 16 oz. was ingested by those who died. Lactose solution (5%) administered for an average of eight days was readily taken by all to an average quantity of 36 oz. Of the remaining 15, 2 died before lactose administration was given. Six received whey (an average of 40 oz. in six days), while the remaining 7 got various foods and subsequently died.

*Subsequent food.* — Seven of the 20 who recovered received at first dilutions of sterilized fat-free milk, strengthened slowly to whole milk; 3 got whey at first, later straight dilutions of milk; 5 buttermilk and 3 straight dilutions of sterilised milk to whole milk. Of the 10 fatal cases that lived through lactose administration no definite result in regard to food can be stated. The majority succumbed to the too early administration of milk or too rapid change of nourishment. The reason for the too early giving of food was the necessity for some nitrogenous nourishment to sustain life.

*Toxic treatment.* — Toxemia, apparent by fever, cold extremities, depressed and at times irritated central nervous system, is fought largely symptomatically. Fever is best kept in bounds by hydropathic means (cool irrigations, packs and baths), while appropriate stimulation for the heart and respiration is administered.

Following the initial treatment comes that of the supplementary treatment. Catharsis is rarely needed a second time except where reinfection occurs. Local gastro-intestinal treatment (colonic irrigation, etc.) is used where symptoms prevail. The main difficulty lies in supporting the child by the appropriate administration of foods and supplying sufficient liquids for the needs of the body.

II. SUPPORTIVE AND STIMULATIVE TREATMENT.

*Supportive treatment.* — The loss of fluids in toxemia resulting from this intestinal infection frequently calls for the hypodermic injection of fluids and medicines as well as the ingestion of stimulants.

Hypodermic injection of the fluids is divided into those given to increase liquid intake (normal salt solution) and salines combined with food and other stimulants.

*Saline infusions* are necessary where ingestion of liquids is impossible or contra-indicated. Indications for such administration are emergencies where prostration, emaciation and rapid loss of fluids are apparent. Another indication is when insufficient liquids are ingested. Such infusions are given at blood temperature, usually under the skin of the abdomen (most convenient), but they can be given subpectorally. *Infusions combined with foods* (dextrose) were considered to increase nourishment. The dextrose used was chemically pure, most essential, to prevent poisoning. It was given in normal saline solution in the strength of 2½%. Of the saline infusions, 12 received from 8 to 20 oz. a day at irregular intervals; 8 of these died and 4 lived. Of the dextrose infusions, 9 patients received such treatment, 5 died and 4 lived. Three to four ounces was the total amount given at a time. The dextrose infusions seemed to stimulate the child far better than the salines and in 3 cases apparently saved life. The administration of such infusions must be checked by urinalysis, and with the appearance of sugar in the urine must cease. One or two such cases were seen.

*Stimulants.* — The stimulants with us were largely given hypodermically. Brandy was very seldom used. Strychnine from 1-250 to 1-500 gr. was given where cardiac failure was imminent (irregular and weak pulse). Camphorated oil and caffein were instituted for the first time but no marked improvement over general knowledge and treatment previous to other years was obtained.

Such as our experience was in dealing with so few patients little can be learned, but as every little helps, for so much is our experience of value. We have definitely found, as we rightly conjectured, that lactose in solution can be given earlier than was formerly considered. Under these conditions it certainly helps ingestion of liquids. We feel that it has a beneficial effect on dejecta spite the fact that this was not born out in the histories. Lactose and dextrose in the irrigations gave no demonstrable therapeutic value. Dextrose infusions were certainly an improvement. While this bacteriological study of movements in connection with bacillary dysentery has not added materially to our knowledge of treatment, it has explained the "whys and wherefores" of our old empirical treatment. In closing may I offer a word of warning. Let us not draw hard and fast conclusions from so new and interesting procedures. What little advances have been made through last year's work should and have born fruit, thus giving us stimulation for further work.

---

THE HARBEN LECTURES. — Dr. Simon Flexner, of the Rockefeller Institute for Medical Research, New York, will deliver the Harben Lectures of the Royal Institute of Public Health of London for 1912. — *Med. Rec.*

## IV. SILVER NITRATE IRRIGATIONS IN THE TREATMENT OF INFECTIOUS DIARRHEA IN INFANTS.*

BY RICHARD M. SMITH, M.D., BOSTON.

VARIOUS astringents have been advocated for the local treatment of the intestine of infants ill with infectious diarrhea. The majority of these astringents have proved entirely useless and the remainder of them are of so little or so inconstant value that they are seldom employed. Weak solutions of silver nitrate have not proved to be better than solutions of other drugs. In the treatment of dysentery in adults, stronger solutions of silver nitrate have been used with apparent success. Hewes has recently published his results from the use of 5% silver nitrate solution. It seems reasonable to expect that, if the ulcers in the intestine can be reached by a sufficiently strong solution of silver nitrate, healing will be hastened, for ulcers elsewhere in the body respond to treatment of a similar nature. Of course only a portion of the ulcers in the intestine are situated near enough the rectum so that they can be reached by substances introduced from below. This, however, does not prevent the treatment of those ulcers which are within reach of rectal irrigation. It is also to be realized that the disease, infectious diarrhea, is more than a local condition of the intestine and that the healing of the ulcers may not mean the recovery of the patient, but certainly no one would fail to use a means of therapy because it did not cure the entire desease, provided some benefit was derived from its use, and no injury was done.

During the last season at the Boston Floating Hospital colon irrigations of 3% silver nitrate were employed in the treatment of infants ill with infectious diarrhea. The technic of the irrigation does not differ essentially from that of ordinary colon irrigations. It is advisable, however, to clean the rectum, and as much of the colon as possible, before using the silver nitrate solution. A cleansing irrigation with sterile water is given and continued until the water comes back clear. Salt solution should not be used for this preliminary cleansing, since the sodium chloride forms with the silver nitrate an insoluble silver salt which is precipitated and the strength of the silver solution is weakened. When the cleansing has been completed, one pint of a 3% silver nitrate solution is allowed to run into the colon and the tube then withdrawn. Some of the solution will be expelled, but no attempt is made to recover the entire amount used. In adults there is considerable pain after the injection, but none of our patients showed any marked evidence of discomfort. Should such discomfort be present, it is easily controlled by an opium suppository. The process may be repeated on the next day, or the next day but one. I do not know how many injections may be given without harm, but, in my experience, if no benefit is derived from three injections, no favorable result is likely to follow further use of this means of treatment.

For the first few hours following a treatment the movements are usually worse than before — more frequent in number and containing much blood. A considerable amount of dirty gray material is expelled with the stools during this time, consisting partly of slough from the ulcers and partly of intestinal secretion and pus acted upon by the silver nitrate. Within the first twenty-four hours, in the favorable cases, improvement begins. The blood in the stools is greatly decreased in amount or entirely absent. In the next twenty-four hours the pus disappears. The movements are less frequent and, provided the patient can be given food, the stools soon begin to assume their normal appearance. Some patients require a second, or even a third, treatment to bring about a completely favorable result. Patients which are not improved by the treatment are not influenced unfavorably. A few infants, who were given this treatment, showed considerable reaction following the injections, but all responded well to stimulation. These infants were very sick and I doubt if the reaction was any greater than it would have been had they received simple irrigations without the subsequent silver nitrate injection.

There were two distinct types of cases in which silver nitrate injections were used. First, the early acute cases, seen during the active period of the disease; second, the subacute or chronic cases, in which blood and pus persisted in the stools after the temperature and toxemia had disappeared. In the acute cases our only methods of estimating the value of the treatment are (1) to judge between the course of the particular cases under observation and what we might have expected the course of that case to have been without treatment; or (2) to compare a large series of cases treated by this method with other series not so treated. This is an unsatisfactory means of judgment, but it is the best we have and the one commonly employed in determining the value of various therapeutic agents. In the chronic cases, it is easier to show a relation of cause and effect between the treatment and the subsequent history of the case, because if blood and pus promptly disappear from the stools after the use of a silver nitrate injection when they had been present constantly up to that time, it seems reasonable to conclude that the treatment was of benefit.

Perhaps the matter may be made clearer by the citation of a few illustrative cases.

E. F., fourteen months old, was admitted to the hospital July 30 with a history of three days' diarrhea, five to ten movements a day. The stools contained blood, pus and mucus. The temperature was 101.5° F.; the general condition was good. The Flexner bacillus was recovered from the stools by Dr. Kendall. On admission, the patient was given 3 drams of castor oil and the next morning received a colon irrigation followed by an injection of 3% silver nitrate. During the next twenty-four hours there were six movements, containing blood and pus. In the next twenty-four

*Read at the meeting of the New England Pediatric Society, Jan. 28, 1911.

hours there were four movements, only one of which contained a little pus with a slight bloody tinge. From that time on the stools remained good except for a small amount of pus, which disappeared entirely by the fifth day. The patient was discharged well.

E. M., four months old, was admitted with a history of bloody diarrhea of two days' duration. The stools on examination contained blood, pus and mucus. During the first thirty-six hours in the hospital there were fifteen stools. At the end of this time she was given a silver nitrate irrigation. During the next twenty-four hours the number of the stools was reduced to three, but they still contained blood and pus. The next twenty-four hours there were three stools, free from blood and pus. One week later a little blood again appeared in the stool. A second injection of silver nitrate was given and the blood disappeared, not to recur again during the convalescence.

C. T., age one year. Was admitted to the hospital July 7, with infectious diarrhea, fever, toxemia and bloody stools. On routine treatment she improved in general condition, but the temperature remained irregular and the stools did not clear. The number of movements varied from seven to twelve in twenty hours, usually nine or ten. Practically all of them contained pus, often in large amounts, and many of them contained blood. On the nineteenth day after admission she was given an injection of 3% silver nitrate. For the next thirty hours the stools were much worse in appearance than at any time since entrance to the hospital. They contained a great deal of pus, considerable blood and slough. Within the next twenty-four hours, however, the blood had entirely disappeared and did not return. The pus was much decreased in amount and only occurred in one subsequent stool. The number of movements in twenty-four hours dropped to four on the second day and averaged four to five during the remainder of the convalescence.

M., seven years old, was seen in consultation Sept. 4. She had had infectious diarrhea for ten days. There was then no fever, but the stools contained blood, pus and mucus and she showed the effects of the long-continued diarrhea. She was given a colon irrigation followed by a silver nitrate injection. A few weeks ago the doctor who had charge of the case reported that the child "was greatly helped by the silver nitrate injection. It seemed to turn the tide of the disease, and I had no occasion to repeat the injection or to turn to other remedies. Recovery was rapid and satisfactory."

The treatment was used at the Floating Hospital in thirty-two cases. In four of these the hospital record gives no account of the result. One patient was *in extremis* on admission and responded to no kind of treatment. One child was taken home within twenty-four hours, so we know nothing of its subsequent history. Twenty-six cases are left from which to draw conclusions. None of the patients were in any way harmed by the treatment. Three infants showed a rather severe reaction, but it was only temporary in character. In twenty-two of the the cases treatments were given early in the disease. Eighteen of these were improved by the procedure, eleven markedly so, and seven slightly. Six patients were given the injection late in the disease. Three, or one half, were benefited.

In a certain number of cases of infectious diarrhea in infants, an early colon injection of 3% silver nitrate solution apparently hastens the disappearance of blood and pus from the stools, and shortens the course of the disease. In some late cases, where blood and pus persist in the movements, the ulcers can be stimulated by silver nitrate injections and the stools cleared. Since no harm has been done by the use of silver nitrate injections, and some good results have been obtained, it would seem worth while to give this means of treatment further trial.

## V. AN ANALYSIS OF ONE HUNDRED AND SEVENTY-EIGHT CASES OF INFECTIOUS DIARRHEA IN INFANTS.*

BY JAMES HERBERT YOUNG, M.D., NEWTON, MASS.

ONE hundred and seventy-eight cases of infectious diarrhea from the wards of the Boston Floating Hospital have been tabulated for this analysis. These comprise all the cases treated during the last two summers, 101 cases in 1909 and 77 cases in 1910.

All statistics compiled from hospital records are open to more or less criticism, especially, as in this case, when the line of work is not planned out beforehand. In order to make, in this series of cases, such criticism less justifiable, records which have not definitely stated the presence or absence of a sign, symptom or other data sought for, have been excluded. A printed form for history and physical examination, used last year, has called for a definite statement of fact on many points which might otherwise have been overlooked. Thus statistics have been made of more value. The cases were first analyzed by years, but as the results were fairly uniform, most of the figures reported are based on the total of the two summers.

### SEX. AGE. RACE.

Males and females were about equally affected, 91 males and 87 females. Nearly half the cases, 41.5%, occurred between the sixth and twelfth months, only 8 cases were less than three months old, and only 5 cases were three years old or over. Mortality was highest in the children less than six months old, 66%; practically the same from the sixth to the twenty-fourth month, 53% to 54%, and 33% for the cases two years of age or over.

| Age. | No. cases. | Mortality. | Percentage of cases discharged well. |
|---|---|---|---|
| Less than six months, | 44 | 66% | 16% |
| Six to eleven months, inclusive, | 74 | 53% | 27% |
| Twelve to seventeen months, inclusive, | 32 | 53% | 28% |
| Eighteen to twenty-three months, inclusive, | 13 | 54% | 33% |
| Two years or over, | 15 | 33% | 33% |

In 65 cases out of the 77 for 1910, the nationality of the parents was given. Irish, Jewish and American parents headed the list with 10 to 15 cases each. Out of the 65, there was but one Italian baby, a fact particularly surprising as the hospital landing is in the heart of the Italian district.

* Read at the Suffolk District Medical Society, Jan. 4, 1911.

### LOCALITY.

During each of the two last seasons, Roxbury has furnished more cases than any other part of the city. The small number of cases from the North and West ends is noteworthy, especially so since they are the most crowded portions of Boston and also nearest to the hospital.

| | Number of cases, 1909 and 1910. |
|---|---|
| Roxbury, | 27 |
| South Boston, | 16 |
| Charlestown, | 16 |
| Cambridge, | 15 |
| South End, | 12 |
| West End, | 11 |
| North End, | 9 |

### DATE OF ADMISSION.

In 1909 more cases were admitted during August than during July, while in 1910 the reverse was true. As the hospital closes Sept. 15, fewer cases are admitted after Sept. 1, so that the number of admissions for the first week in September offers no comparison with the other months. That atmospheric temperature is an important etiological factor is confirmed by an examination of weather reports. July, 1910, was, as a whole, a hot month, the maximum daily temperature being below 80° in only ten out of the thirty-one days. August, 1910, on the contrary, was a cool month, the maximum temperature being over 80° but eleven days out of the thirty-one. The number of admissions during July, 1910, was 45, decreasing during August to 27. A chart of the maximum daily temperature for July and August, 1909, shows four "hot-spells," in each of which the maximum temperature was above 90° from one to three days. The first lasted from July 11 to 17, the second from July 26 to 30, the third from August 7 to 9, and the last from August 25 to 29. The week following each of these "hot-spells," except the last, which extends up to September, and so may be disregarded, shows an increase in the number of admissions over that of the preceding week. Increased susceptibility to heat is denoted by a comparison of the forty-one admissions for July, 1909, with the fifty-five for August.

| Date of admission. | No. cases, 1909. | No. cases, 1910. |
|---|---|---|
| June 29 to July 8, | 4 | 9 |
| July 9 to July 16, | 6 | 14 |
| July 17 to July 24, | 20 | 11 |
| July 25 to July 31, | 11 | 11 |
| Aug. 1 to Aug. 8, | 14 | 9 |
| Aug. 9 to Aug. 16, | 18 | 7 |
| Aug. 17 to Aug. 24, | 18 | 5 |
| Aug. 25 to Aug. 31, | 5 | 6 |
| Sept. 1 to Sept. 8, | 5 | 5 |

### PREVIOUS INFECTIOUS DISEASES.

The statement that infectious diseases predispose to infectious diarrhea is not confirmed by an investigation of these cases. Only 18 cases out of 178 showed any acute infection during the four months previous to the onset of the infectious diarrhea.

### PREVIOUS FOOD.

As the specific etiological factor of the disease presumably enters the body by way of the digestive tract, it is natural we should first turn to the milk for investigation. It was impossible to trace the sources of milk used before entering the hospital, but it is evident, however, that the disease may be contracted by infants fed on the best grades of milk, even when pasteurized. That cow's milk is not the only source of infection is shown by the fact that in three cases of this series breast milk was the only food.

### SYMPTOMS.

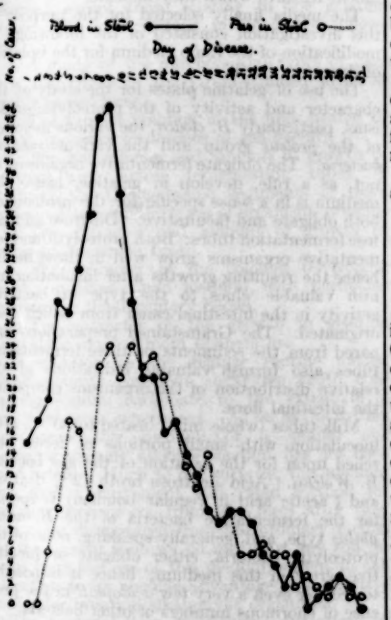
*Fever.* — The presence and persistence of fever is one of the chief symptoms of infectious diarrhea. In the following table, 175 cases are arranged according to the maximum temperature.

| Temperature. | No. cases. | Percentage dead. | Percentage well. |
|---|---|---|---|
| Under 100°, | 47 | 36% | 32% |
| 100.2–102°, | 63 | 50% | 27% |
| 102.2–104°, | 52 | 61% | 19% |
| 104.2–106°, | 13 | 100% | 0 |

This table shows that the mortality increases directly with the rise in temperature. In 13 cases in which the temperature was above 104°, the mortality was 100%. In 44 cases discharged well the average duration of fever was 12.6 days. In 9 of these 44 cases the temperature was under 99°.

*Diarrhea.* — The statements of the mothers in regard to the number of movements before entrance were too indefinite for tabulation. Here again the 44 cases discharged well were studied. There was no diarrhea in 8 cases. The average number of movements was five to six in 24 hours. The average duration of diarrhea was 14 days.

*Vomiting.* — The presence or absence of vomiting was mentioned in 138 out of the 178 cases. Among these vomiting was a prominent symptom in 99, or 71%.



*Prostration.* — In 147 cases, prostration on entrance was mentioned. It was absent in 78, moderate in 49 and marked in 20 cases.

*Blood and pus in stools.* — The occurrence of blood and pus in the stools is shown in the following table.

| | Cases. | Per cent. |
|---|---|---|
| Blood absent in | 21 | 11.8 |
| Blood present in | 157 | 88.2 |
| Blood alone, present in | 56 | 31.4 |
| Blood and pus present in | 101 | 56.7 |
| Pus absent in | 67 | 37.6 |
| Pus present in | 111 | 62.3 |
| Pus alone present in | 10. | 5.6 |
| Mucus was present in all cases. | | |

The cases were next tabulated to find on which days of the disease blood and pus were most commonly found. All cases which had been sick more than ten days before entrance were disregarded. This figure was chosen arbitrarily to exclude if possible those cases starting as an acute intestinal indigestion and later having an infectious diarrhea superimposed, and so to tabulate only those cases which were infectious diarrhea

from the beginning. It was found, when represented graphically, that the line denoting the occurrence of blood rises rapidly, reaching its summit on the eighth and ninth days, when blood was present in 45 and 46 cases respectively. The line then falls sharply, reaching 21 cases on the twelfth day and from then on drops gradually to 0 on the thirty-second day. The line representing the occurrence of pus in the stools reaches its highest point on the ninth and eleventh days, when pus was found twenty-four times. From the eighth to the fourteenth day the line fluctuates between 21 and 24 cases, and from then on follows the blood curve, reaching 0 on the thirty-third day.

DURATION OF DISEASE.

The average number of days in the hospital for the fatal cases was 10.6. Thirty-two per cent of these died within the first five days. In the cases discharged well, the average number of days in the hospital was 26.8, and for those discharged improved, 23.5. The duration of the disease based on the statement of the mother as to the duration of illness before entrance, and the length of stay in the hospital, was as follows:

| | Average duration of disease. |
|---|---|
| Discharged well, | 36.8 days |
| Discharged improved, | 37.8 " |
| Discharged dead, | 20.6 " |

COMPLICATIONS.

One or more complications occurred in 78 out of the 178 cases.

| | Cases. |
|---|---|
| Acute otitis media, | 48 |
| Eclampsia, | 12 |
| Bronchitis, | 7 |
| Bronchopneumonia, | 5 |
| Multiple abscesses, | 4 |
| Nasopharyngitis, | 2 |
| Lobar pneumonia, | 2 |
| Scarlet fever, pyelitis, "weak heart," meningismus and meningococcus meningitis, | 1 case each |

It is doubtful if any other series would show such a large number of middle-ear infections. Their frequency is probably due to the sudden changes in temperature to which patients on a boat are subjected, and also to seal on the part of the house-officers, who are trained to look for them.

Relapses were uncommon. In only 4 cases out of the 178 did relapses occur. Two cases were admitted with a history of infectious diarrhea four and six weeks before entrance, and two had relapses while in the ward.

The condition on discharge of the 178 cases was as follows:

| | Cases. | Per cent. |
|---|---|---|
| Discharged dead, | 96 | 53.9 |
| Discharged well, | 44 | 24.7 |
| Discharged improved, | 17 | 9.6 |
| Discharged unimproved, | 5 | 2.8 |
| Discharged against advice, | 16 | 9.0 |

The mortality of infectious diarrhea as given in series of cases previously reported varies from 6% to 50.9%, the latter in cases in which the dysentery bacillus was found. Such variations only show the difficulty in making a diagnosis of this disease from clinical signs. The severe types are easy to diagnose. It is the mild cases that we overlook, the class of case impossible to diagnose on clinical signs alone, but only by bacteriological examinations of the stools. It is these mild cases which, as dysentery bacillus carriers, form the most common source for the spread of the disease.

## VI. THE ASSOCIATED FLORA OF BACILLARY DYSENTERY.

BY ARTHUR I. KENDALL AND ARTHUR W. WALKER.

(From the Department of Preventive Medicine and Hygiene, Harvard Medical School, and the Boston Floating Hospital.)

THE numerous investigations made in the past upon the intestinal bacteria have been rather closely limited to the morphological and cultural studies of isolated organisms. This method of procedure was the logical one for the earlier observers to follow, and their work was richly rewarded; some of the best-known organisms pathogenic for man were discovered in this way, and the establishment of the etiological agents of cholera, typhoid and dysentery will always be regarded as monuments to their skill and perseverence. The number of diseases in which it has been possible to establish a single organism as the causative agent, however, appears to be limited, and with the methods commonly used this limit seems to have been closely approached.

Notwithstanding the fact that the recognition of these organisms has played a prominent rôle in the diagnosis of these diseases, but little real progress has been made along therapeutic lines, so far as treatment directed against the organisms themselves is concerned; indeed, even at the present time we are ignorant of the conditions which permit these bacteria to gain and maintain themselves in the intestinal tract. We are equally in the dark concerning the symbiotic relations which these exogenous invaders exhibit with the normal intestinal flora.

The studies recorded here, the logical sequence of work which one of us (A. I. K.) has been carrying on for nearly three years, were undertaken with the definite object in view of investigating certain of these underlying causes which permit the unrestrained development of dysentery bacilli in young children. Throughout this work particular attention was directed to the phenomena relating to the biochemistry of this pernicious flora, and as the result of these observations a deliberate attempt was made to bring about conditions in these dysentery cases which should be beneficial to the patient, but which were directly aimed to render the intestinal medium unsuited for the continued development of the dysenteric flora.

It should be stated that the patients upon whom these studies were made were young, with immature and badly upset digestive powers, with limited powers of resistance, and in almost every case seriously or dangerously ill. It is obvious that in such cases it is almost impossible to carry out intensively even the simplest dietary changes which might be indicated from the bacterial standpoint for fear of destroying the already weakened host. This limitation has constantly been kept in mind, and the procedure evolved (which appears in detail in another paper) was elaborated upon this basis.

The procedures followed throughout this work deserve comment. They were designed for practical use by clinicians, and for this reason all complicated technic, and observations requiring several days for their completion, have been reduced to a minimum. The whole idea has been to elaborate a technic which can be carried out advantageously by clinicians who have access to a laboratory provided with the more common appliances. These methods have been found to be practical in studying the intestinal bacteria of experimental animals, and the results of the summer's work indicate that they are equally applicable to the study of human problems of a similar nature.

The salient feature of this investigation is the consideration of the nature of bacterial activity in the intestines rather than the isolation of individual strains of organisms for intensive study; that is, whether the putrefactive or the fermentative types of organisms dominate, and in a general way the measurement of the intensity of these processes. While the interest has centered largely upon the character of the bacterial activity rather than upon the presence or absence of specific organisms, the latter have not been wholly neglected. Those bacteria which either because of their pathological properties or numerical relations appear to be significant have been sought for as well. For this purpose, special media and methods have been invented in several instances. These methods have reduced the time and labor of isolating and identifying these organisms to a minimum. This has been accomplished through the utilization of special enrichment media and by taking advantage of important chemical properties of these bacteria.

The various procedures employed have been described in previous communications, but they will be referred to here in order to bring out the salient features which they indicate.

The media finally selected for the purpose of this investigation consisted of the following: A modification of the Endo medium for the isolation of dysentery bacilli.

The use of gelatine plates for the study of the character and activity of the proteolytic organisms, particularly *B. cloacæ*, the various members of the *proteus* group and the various *subtiloid bacteria*. The obligate fermentative organisms do not, as a rule, develop in gelatine, hence this medium is in a sense specific for the proteolytes, both obligate and facultative. Dextrose and lactose fermentation tubes: Both proteolytic and fermentative organisms grow well in these media, hence the resulting growths after incubation furnish valuable clues to the type of bacterial activity in the intestinal canal from which they originated. The Gramstained preparations prepared from the sediments of these fermentation tubes also furnish valuable indications of the relative distribution of the organisms composing the intestinal flora.

Milk tubes (whole milk) heated to 80° C. after inoculation with small portions of feces were relied upon for the isolation of the gas bacillus, *B. Welchii*. Acid dextrose broth (2% dextrose and $\frac{1}{2}$ acetic acid in regular bouillon) is specific for the fermentative bacteria of the *B. acidophilus* type, and, generally speaking, none of the proteolytic bacteria, either obligate or facultative, grow in this medium; hence it is possible to recover even a very few *acidophili* in the presence of enormous numbers of other bacteria.

Gram-stained preparations made from the feces direct also were found to furnish valuable information, which will be discussed later.

Stools were collected in anal tubes invented by one of us (A. I. K.). These tubes consist essentially of a piece of quill tubing, of glass, about 5 inches long, and 5 mm. inside diameter, with the ends slightly rounded in the flame to prevent injury to the anus when they are introduced. One end of such a tube is plugged rather tightly with a short plug of cotton. The whole apparatus, thus prepared, is enclosed in a stout test tube, the test tube plugged with cotton in the usual manner, and sterilized in the hot air oven. The plug of cotton in the anal tube serves a twofold purpose: it prevents the feces from filling the tube too full, and, when it is desired to empty

the enclosed feces, a wire may be pressed against the cotton in such a manner that it acts as a piston, forcing the contents out in any desired amount.

The technic for the examination of stools adopted for these dysentery cases was as follows:

The stool was collected in the anal tubes in a fresh, uncontaminated condition by simply inserting the anal tube for about three inches into the rectum of the patient; the feces usually flow readily, but at times a second or third trial may be necessary if there is much mucus. The anal tube is replaced in its holder (test tube), brought immediately to the laboratory, and inoculated into the media mentioned above. At the end of eighteen hours all the observations may be recorded except those relating to the gelatine plates. The observations included the following:

1. A study of the numbers and types of bacteria discernible in the Gram-strained fields of freshly passed feces.

2. The type of reaction in the milk heated to 80° C. (presence or absence of gas bacilli).

3. The gas volume, and amount of growth in dextrose and lactose fermentation tubes. A study of the Gram-stained sediments of these tubes to determine the types of organisms present.

4. The character and amount of growth in acetic-acid-dextrose broth.

5. The character of the colonies developing in the modified Endo medium, with particular reference to the dysentery bacilli.

6. The character of the growth in gelatine after three days at room temperature.

In addition to the regular routine media, alkaline broth (nutrient sugar-free broth containing sodium carbonate to the extent of $\frac{N}{5}$ was tried as an experiment. So far as the writers are aware, this medium, or a similar one having a strongly alkaline reaction, has not been used before. Much to our surprise, this medium furnished a convenient and rapid method for isolating *streptococci* from the feces after they had quite disappeared from the ordinary media. At the present time we do not draw any conclusions from the use of this medium except to call attention to its possible advantage as a selective means for isolating alkaliphylic organisms.

The bacterial flora of bacillary dysentery, as it was seen on the Floating Hospital during the summer of 1910, may be divided into three groups. The first group comprises the obligate dysenteric organisms together with other bacteria which are frequently but not necessarily associated with the obligate organisms. The second and third groups represent the bacterial changes which occur in the intestinal flora of these patients following the feeding of lactose.

*Group 1.* — Three prominent organisms make up the "obligate dysenteric flora," — *B. dysenteriæ*, *B. coli* and the streptococcus. In addition, liquefying bacteria, culturally similar to *B. cloacæ*, members of the proteus and subtilis groups, and rarely other liquefying organisms occur. These organisms represent a typical putrefactive flora, growing in the intestinal secretions in the absence of carbohydrate.

*Group 2.* — Transitional flora following the administration of lactose. The bacteria comprising this group, as the name indicates, are transitional between Group 1 and Group 3. They include representatives of the putrefactive flora characteristic of the true dysenteric dejecta, and in addition greater or lesser numbers of the fermentative organisms belonging to the fermentative flora. This group is less sharply defined than the two other groups.

*Group 3.* — The bacteria of this group are the antitheses of the putrefactive organisms characteristic of Group 1. They consist of two distinct types of organisms. The obligate fermentative bacteria, *B. bifidus* and *B. acidophilus*, and in addition a certain number of facultative organisms which have become fermentative in their metabolism instead of putrefactive. Prominent among the latter class is *B. coli*. The numbers of *B. coli* appear to be considerably reduced following the lactose regimen, and they are distinctly fermentative in their metabolism instead of being proteolytes. The streptococci and dysentery bacilli largely disappear when the fermentative flora is well established.

It is a significant fact that *B. bifidus* appear to be relatively more abundant than *B. acidophilus*. The latter organism is more prominent if the patient is fed dextrose or maltose. The absence of excoriated buttocks in the 39 cases studied is partly attributable to the prominence of *B. bifidus*, and the relative absence of *B. acidophilus*. *B. acidophilus* forms a greater amount of lactic acid than *B. bifidus*, and we attribute the absence of excoriations to this fact. The flora developed as the result of feeding lactose resembles rather closely that of a normal breast-fed baby.

The results obtained by this procedure may be summarized in a few words. In the first place it must be remembered that in no case was it possible to study the stools every day. The number of patients under observation and the amount of work necessary to complete one set of specimens made it necessary to choose between two alternatives: to study a very few cases in great detail, or to make fewer observations upon a considerable number of patients. Each method has its advantages, but the latter was the one selected and followed.

Typical dysentery feces from well-marked cases consist microscopically of mucus, usually blood and pus, and only a few bacteria. Not infrequently it is almost impossible to find any bacteria in Gram-stained preparations, unless one searches the preparation diligently. The few that are discernible are of two types: short, almost oval, Gram-negative bacteria, of the *coli-dysentery* type, and Gram-positive cocci, occurring singly, in pairs or short chains. These are streptococci, and they were present in every case. In spite of the fact that there were few bacteria in the stained preparations, good growths were always obtained in cultures.

This relative absence of bacteria, together with the pus, and blood, is a very characteristic picture, and while a definite diagnosis of dysentery cannot be made upon it alone, it is very suggestive.

The dysenteric feces inoculated into fermentation media, dextrose and lactose, produce considerable amounts of gas after eighteen hours' incubation, and the sediments from these tubes stained by Gram's method show large numbers of Gram-negative bacilli, and Gram-positive cocci in chains, of the same morphology as those seen in the direct fecal preparations. The organisms are the same, and consist largely of *B. coli*, *B. dysenteriæ* and the streptococcus. No gas bacilli were found in a true case of dysentery, at least during the acute stage.

A longer or shorter time after lactose feedings are started, the fecal flora undergoes a rather striking change. The streptococci tend to disappear, the colon and dysentery bacilli diminish in numbers, and longer, slender Gram-positive rods take their place. The numbers of bacteria in the dejecta increase considerably in numbers as well.

In the more favorable cases, the flora which results from the administration of lactose resembles that of a normal nursling except that there are relatively more Gram-negative forms referable to the *B. coli* type. The whole cultural complex changes from the aerogenic, putrefactive type to the acidogenic, fermentative type of flora. The length of time necessary to bring about this change varies somewhat and depends, in part at least, upon the numbers and activity of the residual fermentative flora which succeeds in surviving the starvation period in which all food is withheld from the patient.

While the change from the putrefactive to the fermentative type of bacterial activity is, from the standpoint of bacteriology, a favorable sign, it does not always guarantee recovery on the part of the patient. In certain cases, the patient dies after a longer or shorter time in spite of the improved conditions in the intestinal tract, and these fatal cases group themselves into two classes: Those in which the toxemia has been so great that they die from the effects of the poison, and those cases in which the after feeding has been improper.

Unfortunately it is not possible to measure the extent of the toxemia, and it is equally difficult, at the present time at least, to select the most advantageous food to replace the lactose.

The whole question of treatment and after treatment is as yet unsolved. The results, however, from the bacterial standpoint, are highly suggestive, and while these results are as yet incomplete and inconclusive, allowance must be made for the fact that the methods, and the theory which they illustrate, are in the formative stage. Enough has been accomplished to demonstrate the practicability of changing the character of the bacterial flora in the intestinal tract, and it now remains to follow this new line of investigation as far as possible, to define its limitations, and to bring out to the fullest degree its possibilities.

## VII. TWO METHODS OF OBTAINING HUMAN MILK FOR HOSPITAL USE.

BY PEITE B. TALBOT, M.D., BOSTON.

The question which frequently comes up before hospital administrations and their visiting staffs is, How can human milk be procured for the dangerously sick babies within its jurisdiction? In the majority of instances the proposition is hardly discussed but is passed over as something impractical and impossible. Since it has been my fortune to be connected with two hospitals which have procured human milk for their babies with very little difficulty, the object of this paper is to show how breast milk may be obtained in two distinctly different but practical ways. The examples of these two ways are the hospital of the Massachusetts Infant Asylum and the Boston Floating Hospital.

### HOSPITAL OF THE MASSACHUSETTS INFANT ASYLUM.

The hospital of the Massachusetts Infant Asylum, which uses the method of most foreign hospitals, has resident wet nurses who are part of the organization of the institution. These women, secured from other charitable institutions, such as the Society for Helping Destitute Mothers and Infants and from the lying-in hospitals, usually come to the hospital about two weeks after delivery and often are under its care some little time before they are strong enough to bear the strain of supplying milk for more than one baby. Before they are admitted, the mother and child are both examined by the member of the visiting staff on duty for any acute or chronic infectious disease or any physical defect. During the time of probation, each woman is taught the care of her baby under the supervision of a trained nurse and later is given some light work in addition to the entire care of her child. At one time, when they were made to do the laundry work of the whole hospital, it was found that the mothers all contracted "chronic sore throats" and it was decided, therefore, that they should not be permitted to do any heavy work or scrubbing, but should only dust a certain number of rooms and do their own washing.

The amount of food which these mothers require is surprising. They are allowed to have as much as they want of a liberal diet which costs the hospital only 43 to 45 cents a day for each person. The following diet and routine give an idea of their day:

6.30 A.M. Rise and dress.
7 A.M. Breakfast: One pint bowl of mush with milk and sugar. Tea once daily. Every other day eggs or light meat or hash.
10 A.M. Luncheon: One quart bowl of cocoa shells or milk with bread and butter (sometimes one woman drinks two bowlfuls).
12 M. Dinner: Occasionally soup. Always meat (veal, roast beef, corned beef, steak, etc., or ham and eggs), cocoa, potato, carrots, peas, corn, beans, etc. Dessert, custard pie, etc.
1–3 P.M. Bed and sleep or rest.

3 P.M. Luncheon: One quart bowl of cocoa or milk and crackers.

5 P.M. Supper: Cold meat, bread and butter, prunes or apricots and ice cream three times a week.

9 P.M. Mush or cocoa shells (one pint bowl).

There has been only one instance of indigestion from overfeeding during three years, and the general condition of each one has improved under the hospital régime.[1]

The milk of these wet nurses is used in two ways: (*a*) The milk is drawn with breast pumps for the very weak and delicate babies. Although this is often a tedious process, certain women have been able to "draw" more than one quart of milk daily. The milk drawn in this way is placed in sterile jars and kept in an ice-chest until used. (*b*) The stronger babies are put to the breast. The amount of milk taken is recorded by a trained nurse, who weighs the baby before and after nursing. The women are paid according to the amount of milk they supply, at the rate of two cents an ounce for "drawn breast milk" and one cent an ounce for nursed breast milk, up to a limit of sixteen dollars a month.

If these women become troublesome they are sent back to the charities from which they came; but since they are put on their own honor and have so little time on their hands, they rarely create any disturbance. Once a week they are allowed "afternoons out" with the understanding that they are to return before 6 P.M. Each woman stays on an average six to eight months and gives about one quart of milk daily. At this institution there are five wet nurses in the winter, who supply sufficient milk for twenty-four babies, but when the hospital is full of very sick babies, six wet nurses are necessary. Only the very sick and premature babies receive human milk alone; those convalescing are fed on some suitable milk mixture preparatory to their going home.

### BOSTON FLOATING HOSPITAL.

When it decided to obtain human milk for its babies, the Boston Floating Hospital found that the method used at the Massachusetts Infant Asylum was not practicable. Instead, it adopted a plan followed successfully by Dr. Francis P. Denny and reported in the BOSTON MEDICAL AND SURGICAL JOURNAL, vol. clviii, 1908, pp. 625–630.

Dr. Denny says: "The milk was collected by Mrs. A. M. Henderson, a trained nurse. After visiting a large number of nursing mothers in the tenement district, a few were found who had a superabundance of milk. These mothers and their babies were all examined by me and found to be healthy before the milk was used. Precautions were taken to have the milk drawn in a cleanly manner, and put in sterile bottles and then kept at a low temperature. The ability of the mothers to draw off the milk increased markedly after the experience of a week or two. One mother was able to give us over one quart a day. As the milk was taken only from mothers who had more milk than their own babies required, all of the babies continued to thrive while the mothers were contributing the milk. Moreover, the general comfort and prosperity of the family was materially increased by the money which was paid for the milk."

This scheme, as far as I can find out, was original with Dr. Denny and had not been used by any one else until it was adopted by the Boston Floating Hospital, which was fortunate in obtaining the services of Mrs. Henderson, who was familiar with the work and its problems. Mothers willing to supply some of their extra milk were examined by one of the physicians to the hospital for signs of tuberculosis and syphilis and when found free from these diseases were reported to the hospital as suitable wet nurses. Each woman's family physician was then required to sign a card stating that in his opinion it would do her no harm to supply this milk. *In every instance the milk supplied to the hospital was in excess of the needs of their own babies.* In the words of the nurse in charge, "In all cases, notwithstanding the giving of much or little, their own babies are growing like weeds." The women were paid at the rate of sixty cents a quart.

After giving the mothers proper instruction about cleanliness, the nurse had no serious trouble about getting the milk. She refused to accept any really dirty person. Each day a sterilised bottle, with a stopper of absorbent cotton, was left at the house, and the mother drew the milk into the bottle. These bottles were gathered daily and carried packed in ice to the hospital. In several instances drug stores voluntarily acted as centers of collection and distribution. About four quarts of this milk were collected daily. The movement became so popular that many of the mothers were unwilling to accept any recompense. The nurse's report comments thus on this generosity: "Another apparently poor woman, after being consulted twice about remuneration, said positively, 'No, I couldn't; Charity has been good to me, and if I can return it, I am glad to do it.' She is so conscientious that she will not 'go away for Sunday and have my sick babies without my little contribution.' Another, upon receiving a letter of thanks from the hospital, said, 'I'd rather have this letter than $25.00.'"

There was no public list of nursing mothers which could be utilized, so for that reason the nurse had to depend upon her own efforts and ingenuity. She was, however, familiar with the work in general and knew the local physicians, for many of whom she has nursed. At first, possible wet nurses were found with difficulty, but later the word was passed around among the women in the district until finally both physicians and patients sent the names of other mothers who were willing to supply milk.

Although these four quarts of human milk collected daily were not enough to supply one tenth of the babies who needed it, I feel certain that the lives of most of the babies who did get it would have been lost without this means of

[1] These women are under the charge of Miss Allen Chaney and Miss Greta Mabry.

treatment. As many babies as possible were given human milk, sometimes in small or again in larger doses. These infants almost invariably did so well that it was not uncommon to see them quickly regain their powers of digesting cow's milk. With such encouraging results in these few cases we hope to have more milk at our disposal next summer and to use it for a greater number of the babies.

Both these methods of obtaining human milk are practical, and with a small financial outlay one or the other can be adopted by any hospital. Since each plan has been followed successfully in two different types of hospital, no one need say that human milk cannot be had for hospital use, because with sufficient ingenuity it can be obtained.

## VIII. DIARRHEA IN INFANTS ASSOCIATED WITH THE GAS BACILLUS IN THE STOOLS.*

BY ARTHUR I. KENDALL, PH.D., AND RICHARD M. SMITH, M.D., BOSTON.

*Bacillus aerogenes capsulatus* or the gas bacillus (*Bacterium Welchii*) was first discovered by Prof. William H. Welch, of Johns Hopkins Medical School, in 1891, and described by Welch and Nuttall in 1892.

In 1893, W. Fraenkel published the description of an organism which he isolated from a case of gas phlegmon, and this latter organism, together with the bacilli known as *Bacillus perfringens* (Veillon and Zuber), *Bacillus enteritidis sporogenes* (Klein) and *Granulo-bacillus immobilis liquefaciens* (Grasberger and Schattenfroh) all appear to belong to a well-defined group, if, indeed, they are not the same organism.

These bacteria, of which *Bact. Welchii* is the type, are rather thick, plump, Gram-staining rods, which form spores in most instances, although sporulation is not infrequently difficult to bring about. The organisms are obligate anerobes, and usually form capsules in the animal body. They liquefy gelatine, ferment several of the more common sugars, and grow characteristically in milk, producing a "stormy fermentation," evolution of gas and liberate considerable amounts of butyric acid.

According to many observers, these organisms are rather widely distributed in nature, occurring in dust, the excrement of man and the higher animals, in many samples of market milk and in enormous numbers in sewage. It is not, however, a normal inhabitant of the intestinal tracts of normal nurslings after the first two days of the meconium.

The pathogenic powers are variable; certain strains, according to Dr. Theobold Smith, form toxins if they are grown in media containing minimal amounts of sugar. The gas bacillus usually shows rather marked hemolytic powers.

The interest that attaches to the gas bacillus so far as it relates to the work presented here is in relation to its presence in the intestinal tract. It is, as was stated above, very uncommon in the intestines of normal nurslings, not infrequently present in the stools of bottle-fed babies in small numbers, and is usually found in the dejecta of normal adults, to a greater or lesser degree. In spite of the presence of this organism in the feces of man, comparatively few observations are recorded in which it is the causative agent of diseased conditions in the alimentary canal.

Howard, however, has shown that there are instances of more or less extensive superficial necroses of the gastro-intestinal tract associated with the presence of unusual numbers of the gas bacillus, and Tissier has studied cases of acute and "subacute intestinal catarrh" in which these organisms were unusually numerous. These latter cases, as a rule, ran a mild course, and appear to have been associated with a deficiency of carbohydrate (?) in the patient's food. Nobecourt and Rivet, Guillemot and Szczawinska and others have also found these bacteria in acute and subacute enterocolitis. Klein has isolated a similar organism (*B. enteritidis sporogenes*) from the stools of patients in an outbreak of diarrhea, and Andrewes has studied three distinct outbreaks of a benign type of diarrhea which occurred in St. Bartholomew's Hospital in London in which gas bacilli were present in the stools of the patients, and in the milk which was incriminated as the cause of the outbreak. One hundred and forty-six persons were taken ill in one night in one of these epidemics. The prominent clinical features of these cases were abdominal pains, fluid and semifluid stools, with frequently blood and mucus and a relatively short duration of the attack.

In the vast majority of cases, aside from the so-called "foamy organs," the gas bacillus appears to be a saprophyte living upon the intestinal contents rather than a true invading organism, and this statement agrees well with the experience of last summer in Boston. *B. coli* frequently appears to be also present in unusual numbers in certain of these cases, and Sittler believes that *B. coli* and the gas bacillus act together symbiotically in many of these cases. Our experience does not prove this to be a fact, but the evidence certainly is not against such a supposition.

Tissier, as the result of his studies, has arrived at the conclusion that a diminution of carbohydrate is responsible, in many instances, for the overgrowth of the gas bacillus; our studies lead us to believe that lactose (and possibly other sugars, particularly in diarrheal cases where there is ample opportunity for the intestinal bacteria to be largely removed by the repeated evacuations), is of distinct harm, and that the withdrawal of all carbohydrate, temporarily at least, and the substitution of sour milk, is the proper treatment to reduce the numbers of these bacteria. It is difficult to reconcile our experience with that of Tissier, but there is no doubt in our minds that in our cases, at least, lactose was distinctly harmful, and its use was followed by a rise in temperature and a general aggravation of the patient's condition, while the substitution of buttermilk worked wonders. Both Tissier and ourselves appear to agree upon the efficiency of sour milk, and these results are in accord with those of Dunn.

* Read before the New England Pediatric Society, Feb. 25, 1911.

Last summer at the Floating Hospital certain selected cases of diarrhea were studied in relation to the bacteriological findings in the stools. Among the routine investigations made was a test for the gas bacillus. This test was done without a definite idea as to what might result, but in the hope that some facts of interest and value would come to light. The method employed has already been described in a previous report, but may be repeated here. It consists essentially in inoculating sterile tubes of whole milk with a small portion of the suspected stool thoroughly emulsified in it and immersed in a water bath to above the level of the top of the milk and heated to 80° C. for twenty minutes, then incubating at body temperature for eighteen to twenty-four hours. As an alternative procedure, the infected milk tube may be gradually brought to the boiling point of water in a water bath, kept there for three minutes, then incubated as above. By so doing, all bacteria not in the spore state are killed and the development of whatever spores may be present into vegetative cells is unrestrained by the presence of non-spore-forming organisms. Those cultures containing gas bacilli present at the end of the period of incubation three prominent features: (*a*) The casein is largely dissolved (usually at least 80%); (*b*) the residual casein is slightly pink in color and filled with holes, the result of the stormy fermentation; (*c*) the odor of the culture strongly suggests that of rancid butter, due to the formation of butyric acid by the gas bacillus. Gram-stained preparations made from such growths show rather thick, short, Gram-positive bacilli with slightly rounded ends. Controls suitably studied have shown that cultures presenting this complex are in reality gas bacilli.

Very frequently "pseudo-reactions" occur; there is, as above, a decided liquefaction of the casein, but the shotted appearance of the residual casein is absent and there is no odor of butyric acid. These growths have been found to contain *B. subtilis* or members of the subtilis group, and are not to be regarded as even suggestive of *Bact. Welchii*.

This method has several things to be said in its favor. In the first place, it is simple. No special medium has to be prepared, no careful technic is necessary to assure accurate results. In the second place, it is rapid. The diagnosis by this method can be made by the end of twenty-four hours. In the third place, it appears to be reliable. As has been stated above, suitable bacterial controls prove that when this reaction is present the organism causing the reaction is the gas bacillus.

In the routine application of this test to the stools examined the results were negative in the vast majority of instances, but during the course of the summer certain cases were found in which it appeared that gas bacilli were playing an important rôle in causing the diarrhea. Therefore, it seemed worth while to make an examination of a large number of stools to determine if possible the distribution of these organisms. The stools examined were for the most part derived from Floating Hospital cases; a few were secured from other hospitals and certain private cases. Many of these were normal stools, others showed some undigested material and still others contained mucus, pus and blood in varying amounts. All together there were examined 293 stools, which from our results naturally divided themselves in three groups. (1) Those in which no gas bacilli were found. These were 271 in number and require no further comment except that the great proportion of stools in which the test was negative showed that the gas bacillus is relatively rare in the stools of infants and young children. (2) Those in which few bacilli were present, 8 in number. It is well known that the gas bacillus not infrequently occurs in older children on mixed diet and, as has been pointed out by other investigators, it may sometimes occur in infants. The bacilli were so few in number in these cases that they apparently are of no significance except that it is possible that under certain conditions the organisms might multiply and the cases would then fall into the next group. (3) Cases in which the organisms are very numerous, 14 in number. The organisms in this group occur in such numbers and relations as to warrant the assumption that they play an important rôle in the causation of the disease. The fact that these cases gave a history of long-continued diarrhea or of diarrhea of great severity would make it improbable that the bacteria would remain in the intestinal tract in such large numbers unless they were a causative factor of the diarrhea. The following cases are cited as illustrative of this third group.

E. C., six months old. Was admitted to the hospital Aug. 14. There was a history of eight days' diarrhea and a convulsion the day before entrance. The temperature was 100. There was marked prostration and the next morning the stool contained pus and blood. A diagnosis of infectious diarrhea due to dysentery bacillus was made and the routine hospital treatment for that condition instituted. This was continued for a week, but the child did badly and was growing worse when gas bacilli were found in the stools. It may perhaps be well to explain that, owing to the large number of cases on the boat, only certain cases were selected for bacteriological examination of the stools. This case was not investigated until it had been in the ward a week, which accounts for our not being able to make the diagnosis sooner. As soon as the gas bacillus was found, however, buttermilk was given. This was vomited at first, but after twenty-four hours was well taken and improvement in the condition of the patient and the character of the stools was at once apparent. This improvement continued until ten days later, when the patient developed pneumonia, which proved fatal.

This case is interesting for several reasons. The diagnosis of infectious diarrhea was made from the clinical examination and in another similar case would be likely to be made again. It is of the type which cannot be accurately differentiated without the aid of bacteriological examination of the stools. Gas bacilli were found in the stools, but no dysentery bacilli were present. This has been our experience in every severe case: that the two groups of organisms have not been found to

exist in the same patient at the same time. There was prompt and striking improvement with the institution of the proper treatment. It is not improbable that had the correct diagnosis been made at entrance and the appropriate treatment given, the patient might have been saved. It is in just this sort of a case that we believe the method described will be of definite and permanent value.

C. M., three years. Entered the hospital Aug. 5. A diagnosis of infectious diarrhea was made and he was given the initial starving followed by lactose solution. He also had irrigations of the colon. He did not do well on this treatment. The temperature was high, the pulse irregular and the general condition poor. Two weeks after admission the stools were examined bacteriologically and no dysentery bacillus found, but the gas bacillus was present in large numbers. He was immediately put on buttermilk and as promptly responded. The general condition at once improved and he was discharged well.

This case is interesting as suggesting the possible danger of the treatment of cases as infectious diarrhea which in reality are not such. The day following the giving of lactose to the child the temperature rose to 101 and the next day to 103, for which no explanation could be found. Lactose consequently was omitted and the temperature fell. On resuming lactose it rose again, this time, however, only 1°. This patient also received colon irrigations, but derived no benefit from them. He might have been spared this shock had it been known that there were no ulcers present.

C. T., aged one year, is chiefly interesting as illustrating that gas bacilli may appear in the stool without any red flag of warning. This patient had been in the hospital one month and was convalescing from infectious diarrhea. She was not doing especially well; at the same time the stools were not markedly different from what they had been. In the course of routine examination gas bacilli were found in the stools and she was immediately given buttermilk. Her condition improved gradually from that time on and she was discharged well.

From these few cases it will be seen that there exists a group of diarrheas in infants which it is difficult or impossible to differentiate clinically from infectious diarrhea caused by the dysentery bacillus and in which, apparently, the gas bacillus is the etiological factor. It is to be stated, however, that it is important that this differentiation be made because the treatment which is of value in cases of infectious diarrhea is apparently distinctly harmful to cases of diarrhea caused by the gas bacillus.

The treatment of cases of diarrhea associated with large numbers of gas bacilli deserves a word. The use of buttermilk in certain cases of diarrhea has been tried by many men. In our experience the use of buttermilk in this group of cases has been very satisfactory. In all our cases in which buttermilk was tried the response to treatment was immediate and permanent.

In conclusion, it may be said that apparently there exists a group of diarrhea in infants impossible to differentiate clinically from infectious diarrhea caused by the dysentery bacillus. These cases are associated with the presence of large numbers of gas bacilli in the stools. The bacilli occur in such numbers and in such relations that it seems reasonable to believe that they are the etiological factor of the diarrhea. A simple method for detecting the presence of gas bacilli in the stools has been described by means of which it is possible within twenty-four hours to make a definite diagnosis of diarrhea caused by the gas bacillus. This diagnosis when made gives the indication for treatment with buttermilk. In the application of this method, and the differentiation of this group of cases due to the gas bacilli, a distinct advance has been made in the diagnosis of diarrhea in infants.

## IX. DOUBLE OTITIS MEDIA. DEHISCENCE OF THE FLOOR OF THE CAVUM TYMPANI. STREPTOCOCCUS MENINGITIS.

BY DANA W. DRURY, M.D., BOSTON.

The following case is of interest on account of its rarity:

B. S., aged nine months, was admitted to the wards from the day deck on July 24.

*Past history.* — Weight at birth, 4 lb. Breast fed and negative history up to eight days previous to admission. Family history negative.

*Present illness.* — When first taken ill the baby vomited ten or more times daily. Then more or less vomiting to the time of admission. The baby had temperature of 101° F., with considerable prostration. Sleeps most of the time except when fed and then vomits several times.

*Physical examination.* — Well-developed and nourished child, 14 lb. General condition: Marked prostration, dusky, and eyes rolled up. Pupils equal and react to light, tongue clean.

*Heart:* Sounds regular but poor quality and fetal in character.

*Lungs:* Negative.

*Abdomen:* Level, soft and tympanitic. Knee jerks very lively. No Kernig present.

Both membrana tympani red and bulging, but no perforations. No landmarks seen. No rigidity of neck or retraction. Membrana tympani of the left ear was incised with the usual seropurulent discharge through the wound. The membrana tympani of the right ear was also incised properly by Dr. C. H. Lawrence, Jr., of the house staff, with immediately a profuse discharge of dark blood, not pulsating. The canal of the ear was plugged and the hemorrhage controlled.

When I saw the baby a short time afterwards I found that although tight packing of canal would control the bleeding, on removal of dressing the bleeding would begin again. The origin of the bleeding could not be seen, as I could not keep the canal free from blood. The canal was finally packed and an outside dressing applied. Head raised and to be kept absolutely quiet. Calcium lactate, gr. i, every four hours was used, plus urotropine, gr. v, per rectum, every four hours.

July 25. Slight Kernig and rigidity of neck present; sleeps most of the time. Ear still bleeds when packing is removed. Lumbar puncture showed cloudy fluid with pus cells and chains of streptococci.

July 26. Child unconscious, eyes rolled up

pulse weak, temperature 102° F. Little response to stimulation.

July 27. White count, 13,950; polynuclears, 78%; lymphocytes, 15%; eosinophiles, 6%; temperature, 102° F., with increasing pulse-rate and respirations. Child remained in about same condition as above and died in afternoon on the 28th from streptococcus meningitis.

Immediately after death the canal of the ear was cleaned. Membrana tympani cut away and absence of floor of middle ear found with jugular vein mounting into middle-ear cavity. Passed probe some distance down neck and pressure on neck in an upward direction would flood field with dark blood. Petrosquamosal suture open.

When the lateral sinus is large and unusually far forward the bulb is likewise large and the fossa, which is consequently deeper, may arch up into the floor of the tympanic cavity, from which it may be separated merely by a thin and translucent plate of bone which occasionally shows an osseous deficiency.

Cases have been reported that when the above condition is present the blue color of the jugular vein will show through the lower segment of the membrana tympani and, of course, if present, a paracentesis should be done higher and posteriorly. But with a bulging, congested, edematous condition present, the color of the vein will be lost. Quickly tamponing the canal ought to be sufficient to control the bleeding.

## X. A CASE OF INTUSSUSCEPTION.

BY SETH VINCENT, M.D., BOSTON.

Mary M., an infant of two months, was admitted to the Boston Floating Hospital, Aug. 21, 1910.

She was a breast-fed and perfectly healthy baby up to the day before entrance. At 4 A.M., the child awoke screaming with pain. She was pale but did not vomit. At noon, about eight hours after the onset, the child passed a stool of bloody mucus. She was seen by a doctor in the afternoon, who gave some bismuth and calomel, omitted the breast feedings, and put the child on a diet of barley water. During the night the infant had two black movements. In the morning she vomited for the first time, and passed another stool of reddish mucus with a streak of blood. The mother brought the child to the hospital in the evening, about forty hours after the onset of the attack.

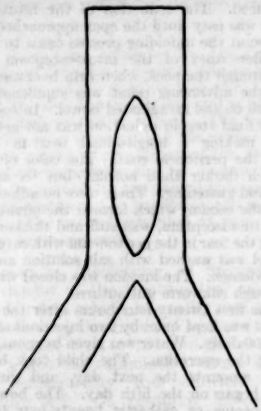
At the time of the examination the patient was resting quietly, apparently not in pain. She was a well-developed and very well-nourished child that looked pale but did not appear sick. The heart and lungs were negative. The abdomen was full and tympanitic, but not distended. There was no spasm in the right lower quadrant, but some resistance in the lower left abdomen which prevented deep palpation. No tumor could be felt. On rectal examination, while there was a sense of resistance high in the pelvis, no definite mass could be felt in the rectum. During the examination, the patient had a small movement, consisting of clear, red blood. The temperature was 101°, pulse 115, respirations 32. A diagnosis of intussusception was made on the typical history, and the infant prepared for operation.

Under ether a deeply placed tumor of indefinite outline and extent could be felt above the pubis. The abdomen was opened by an incision, a little to the left of the umbilicus. There was some free fluid. The tumor proved to be an intussusception, which occupied a vertical position in the left half of the abdomen. The sheath consisted of the sigmoid, the descending and part of the transverse colon. The neck was between the umbilicus and the liver, and the apex extended into the pelvis. The tumor was fairly movable and could be drawn outside the abdomen, where the invagination was reduced. The reduction of the intussusception, as usual, was easy until the apex approached the neck. At this point the unfolding process came to a halt, and the swollen apex of the intussusceptum was only forced through the neck, when firm backward pressure against the advancing point was supplemented by a gentle pull on the invaginated bowel. In spite of some care, the final step in reduction was not accomplished without making a longitudinal tear in the bowel through the peritoneal coat. The color of the bowel was much darker than normal, but its surface was smooth and glistening. There were no adhesions. The head of the cecum, which formed the advancing point of the intussusceptum, was stiff and thickened. After repairing the tear in the peritoneum with catgut sutures, the bowel was washed with salt solution and replaced in the abdomen. The incision was closed with through and through silkworm gut sutures.

For the first twenty-four hours after the operation, the infant was kept quiet by two injections of morphine in gr. 1-100 doses. Water was given by mouth the night following the operation. The child took breast milk in small amounts the next day, and direct breast feedings began on the fifth day. The bowels moved without enema or cathartic twenty-four hours after the operation. On the second day there were seven small dejections, dark in color, growing gradually lighter. Fecal matter appeared in the dejections on the third day. On the fifth day a stitch abscess was opened in the upper half of the wound. The infant was discharged on the nineteenth day after the operation. One month later the child was seen at the Boston Children's Hospital in normal health except for a small hernia in the scar just above the umbilicus.

## XI. A METHOD OF COLLECTING URINE FROM FEMALE INFANTS.

BY CHARLES H. LAWRENCE, JR., M.D., BOSTON.



The apparatus described here was used in a number of cases on the Boston Floating Hospital during the summer of 1910 for collecting specimens of urine from female babies. It is easy to construct and was generally efficacious. It did not seem to bother the patients while in place, and produced no local irritation. It can be used for the collection of twenty-four-hour amounts as well as for single specimens.

The materials necessary are a strip of adhesive plaster an inch and a half to two inches wide and four to six inches long, according to the size of the baby; the thumb of a rubber glove (those no longer fit for surgical use will generally serve), and, for single specimens, a heavy glass test tube. For collecting twenty-four-hour specimens the test tube is replaced by a piece of glass tubing which is connected by rubber piping with a bottle placed beside the bed.

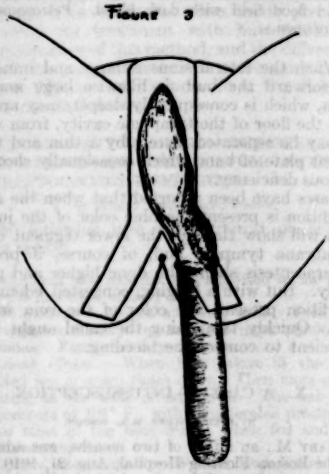
The apparatus is prepared in the following manner: In the strip of adhesive tape there is

cut a hole a little larger than the vulval orifice of the infant from whom the specimen is to be obtained. The end of the strap which is to be applied posteriorly is split into two tails, the cut being carried close to the hole (Fig. 1). The glove thumb, cut as in the diagram (Fig. 2), is

FIGURE 1

dropped, tip first, through the hole in the strap, the adhesive side of which is held uppermost. That part of the rubber thumb which remains above the hole is turned down on to the adhesive surface of the strap and pressed firmly against it, care being taken to have the rubber flange narrow enough so that there will be a band of adhesive

FIGURE 2



surface around it. The tip of the thumb is cut off, the test tube inserted and the joint made tight by wrapping it with adhesive tape.

To apply the apparatus, the strap is placed over the perineum so that the opening in it lies over the vulva, the anterior end extends up on to the lower abdomen, while the posterior tails are directed backward and outward over the buttocks, avoiding the anus (Fig. 3). Gentle rubbing causes the strap to lie smoothly and prevent leakage.

When the strap is in place the vulval orifice is covered by the open end of a rubber funnel through which the urine drains into the receiving vessel. If a single specimen is desired, the heavy test tube may be allowed to rest between the baby's legs, the upper end being slightly raised. For twenty-four-hour amount the rubber piping

FIGURE 3

is led to the bottle on the floor as the tubing in constant drainage of the bladder in adults.

Removal of the apparatus is not painful, the strap peeling off easily. The adhesive tape must, of course, be changed each time the apparatus is used; the glove finger should serve for several cases.

## Reports of Societies.

### SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

TWENTY-THIRD ANNUAL SESSION, HELD AT NASHVILLE, TENN., DEC. 13, 14 AND 15, 1910.

(Concluded from No. 8, p. 273.)

#### A MALIGNANT INTESTINAL GROWTH REQUIRING THE REMOVAL OF AN UNUSUAL NUMBER OF ABDOMINAL STRUCTURES.

DR. THOMAS S. CULLEN, of Baltimore, in his paper reported the case of a patient, fifty-six years of age, very pale and emaciated. Within a few hours prior to operation her weight had been reduced from 120 to 85 lb. Pelvic examination revealed a growth plastered on the posterior surface of the uterus. This almost filled the pelvis and felt very much like a myoma. The patient, however, gave a history of flattened stools

occasionally associated with diarrhea, and a malignant intestinal growth was suspected. On opening the abdomen Dr. Cullen found a growth involving the lower portion of the descending colon, also a loop of small bowel, and extending out and forming a tumor mass in the mesentery of the small bowel. Intimately blended with this tumor mass was the uterus. The appendix was also involved. As the patient's condition was very poor the operator hesitated to do anything, but the family physician said that she could only live a few days in her present condition, and that she was suffering a great deal. As no secondary nodules could be found either in the mesentery, in the lymph glands or in the liver, removal was undertaken. The uterus was amputated through the cervix and with the tubes and ovaries turned up on the surface of the tumor. The appendix was next amputated, carefully covered over with gauze and also turned up on the tumor. About three feet of small bowel and almost a foot of large bowel were then clamped off and the mesentery of the small bowel containing the tumor gradually tied off. All the structures mentioned were removed in one piece, as it would have been absolutely impossible to separate the uterus without entering the cancerous mass and opening up the bowel. It was possible to remove the entire mass without soiling the peritoneum. The four ends of the bowel were closed. A lateral anastomosis was then made between the small bowel and the cecum, and as the descending colon had been redundant it was possible to do a lateral anastomosis between the descending colon and the sigmoid. A drain was laid in the pelvis. The specimen was exhibited. The patient made a very satisfactory recovery and was at present in good health. The ultimate outlook was not a favorable one.

### ANEURYSM.

Dr. J. Garland Sherrill, of Louisville, Ky., reported a case of aneurysm, and described a new method of ligature of the left subclavian. From a study of the reported cases and his own work, the following conclusions were drawn: That ligature of the subclavian artery in the first portion of the right side showed a higher mortality than on the left. This was probably due in part to the short distance between its origin and the first branch, and also to its close relation to the pneumogastric nerve, thoracic duct and the internal jugular vein. The mortality of ligature in the second division is 55.5%; in the third division, about 50%. The mortality was greater when ligature was done for injury to the vessel than for aneurysm. With present methods the mortality of ligature in any portion of the subclavian should be greatly reduced, as was shown by recent results of Halsted, Schumpert, Jungst and Curtis. Distal ligation had not proven satisfactory. When the aneurysm was situated high on the axillary artery or upon the distal portion of the subclavian, the anterior operation should be employed when the vessel was accessible. The method here described was offered for the treatment of those cases in which the aneurysmal tumor encroached upon the tissues of the neck in such a way as to preclude the possibility of ligation by the anterior method. He had found that at the origin of the left subclavian from the arch of the aorta there was no danger of including the pneumogastric nerve in the ligature or of damaging the thoracic duct.

### GOITER OPERATIONS.

Dr. John R. Wathen, of Louisville, Ky., described an improved technic in goiter operations, based upon an experience of 142 operations for the different types of goiter, with no case of injury to the recurrent laryngeal nerve or any clinical evidence of injury to the parathyroids. The use of the scissors had replaced the knife entirely, and all the structures, beginning with the skin, and later the enlarged thyroid gland, were elevated and approached from the under surface. This lessened the hemorrhage by placing the parts on the stretch, made the work more rapid and safer and allowed of easier blunt dissections being made. The neck was opened by pinching up the skin with the fingers, and making a small cut through the skin and the platysma. The cut surfaces were now grasped by vulsellum forceps and traction was made upward; next, blunt-pointed, curved scissors were used as a dissector and the skin with the attached platysma was rapidly separated from the muscles below and then cut along the curved line used by the Kochers. By continuing the upward traction, the two large skin flaps were dissected up to the hyoid bone above, and to the sternum below. The ribbon muscles were now separated in the middle line and clamped high up and cut on one or both sides when needed, as had been suggested and practiced by Dr. C. H. Mayo. The fibrous and the true capsule over the goiter was next opened, and with a large pair of vulsellum forceps, the enlarged lobe was elevated and traction was made in an upward direction and to the opposite side of the neck. This readily allowed the capsule to be dissected downward and placed the blood vessels to be ligated on the stretch, causing less venous hemorrhage, and relieved the trachea of the pressure from the weight of the tumor. The vessels could now be clamped as the elevated goiter lifted them away from the surface of the capsule. The capsule adherent to the posterior structures was thus separated from the vessels, and there was no danger of the nerve being included with the vessels or any danger of injuring the parathyroids. Occasionally, when the enlarged lobe extended high up in the neck, it was better to place on a second vulsellum forceps on the upper part and make traction upward and downward to better expose the superior thyroid artery and vein. This constant upward traction on the tumor allowed it to be rapidly dissected from the posterior structures, and only held by the isthmus of the gland. A large clamp crushed this part, which could be sutured over. The capsule, muscles and skin were now closed in the usual way and drainage provided through a stab wound in the lower flap. This technic differed from that of others in that it did not employ the knife, which was dangerous in neck surgery; it cut the skin and superficial structures, only after they had been elevated and dissected up from below, and it grasped the goiter with vulsellum forceps and elevated it away from the dangerous area underneath. This constant traction caused much less hemorrhage and allowed of a rapid operation, within plain view of the surgeon. It was surprising how few forceps were used when the venous hemorrhage was thus controlled.

### COLLAPSE OF THE TRACHEA WHILE PERFORMING THYROIDECTOMY.

Dr. T. C. Witherspoon, of Butte, Mont., said that during the last fourteen months he had twice had the trachea collapse while performing thyroidectomy for exophthalmic goiter. The predisposing cause of collapse of the trachea was the anatomical defect in the rings posteriorly. This allowed the lateral walls to approach closer under pressure and to change the cross section of the tube from a circle to an oval with its long diameter anteroposteriorly. Another factor influential in starting a collapse was the proximity of the recurrent laryngeal nerve to the thyroid gland. It was possible that more or less softening occurred from the toxic effects of the gland secretions. The one

prophylactic measure which he suggested as a means of avoiding pressing upon the trachea was a para-sterno-cleido-mastoid incision. This enabled the operator to raise the gland out of its bed without medianward pressure of appreciable degree. No doubt a collar incision with enucleation from between the sterno-hyoid and sterno-thyroid muscles of either side necessitated considerable pressure upon the trachea. While working out the problem of removal of the thyroid under local anesthesia, he found it very much easier to do so by the paramuscular than by the collar incision. Manipulation was easier and discomfort minimized. He experimented upon the cadaver in developing a technic and removed over twenty goiters under local anesthesia before using a general anesthetic. This was excluding his first case operated upon in the early nineties to which chloroform was given. Of late years he had used the collar incision, possibly modified slightly, but he was rather of the opinion that his former plan of paramuscular incision gave a better field, made operating easier and did not leave an ugly scar. He believed this incision would prove a valuable prophylactic against tracheal collapse.

CATHETERIZATION OF THE COMMON DUCT AS A PRACTICAL AND EFFECTIVE UPPER ROUTE FOR ENTEROCLYSIS MEDICATION IN TOXIC BILIARY CASES. (MC ARTHUR'S PROCEDURE.)

DR. RUDOLPH MATAS, of New Orleans, related his experience with this operation and said it was a conclusive demonstration of the good effects of this mode of procedure. It convinced him that it constituted one of the most valuable therapeutic assets in dealing with the dangerous post-operative complications of biliary cases. Since his first experience, he had had occasion to try it in another case of choledochus drainage after cholecystectomy or gangrenous and perforated gall bladder. In this case, notwithstanding the excellent effect on the circulation of the duodenal infusion, which was liberally applied, the patient succumbed on the fifth day from the effects of general peritoneal sepsis and exhaustion due to secondary pulmonary infarcts. He had also applied it in three other cases, two referred to him by other surgeons, of persistent biliary fistula after cholecystectomy for multiple calculi and cholecystitis. In these cases he had been surprised by the rapid cure of the fistulæ after repeated catheterization of the biliary tract, including the duodenal orifice of the common duct. In no case had he had occasion to apply the simple procedure recommended by McArthur, which was to connect a saline drip to a drainage tube in the gall bladder, thus allowing the water to find its way into the duodenum via the cystic duct. This was a very simple performance; but in all his cases he had preferred to inject the fluid directly into the duodenum by introducing a catheter through the gall-bladder opening into the common duct and then into the duodenum. For this purpose, he had found nothing so effective as a ureteral catheter beginning with a fine bougie and gradually dilating with the catheters until the number three of the French scale had been reached.

SOME SUGGESTIONS RELATIVE TO THE PREPARATORY OPERATIVE AND POST-OPERATIVE TREATMENT OF CASES OF ACUTE INTESTINAL OBSTRUCTION.

DR. JOHN YOUNG BROWN, of St. Louis, Mo., stated in this paper that an analysis of the records of 59 cases of acute intestinal (mechanical) obstruction coming under his care with the view of ascertaining the treatment received in each case prior to operation and the bearing this treatment had on the mortality had convinced him that the general profession had yet to appreciate that acute intestinal block was one of the gravest and most disastrous surgical emergencies, and that the outcome of a given case depended largely upon the time elapsing between the development of the condition and its relief by surgical interference. Of the 59 cases recorded, 27 required primary resection for gangrene of the bowel. All of these cases save one resulted from strangulation due to hernia, the exception being due to a gangrenous intussusception. Of these 27 cases, 5 died, giving a mortality of a little over 20%. In 12 cases the formation of an artificial anus was necessary. Three of these were for strangulated umbilical hernia, 4 for strangulated inguinal hernia, and 5 were for acute obstruction due to malignancy. Of these 12 cases, 6 died, giving a mortality of 50%. Twenty cases of strangulated inguinal hernia in which the contents of the sac was such that it could be returned to the abdomen resulted in the loss of one case, a mortality of 5%. The total mortality in the 59 cases was a little over 20%, a mortality entirely too high and largely due to conditions avoidable. The history of each case without a single exception showed that temporising methods were resorted to prior to operation. He illustrated this by selecting two cases at random from the list, one operated on fifty-two hours after strangulation, the other seventy-two hours. Gangrenous bowel was found in each. Taxis, cathartics and morphine, with hot applications to the abdomen, had been used in each case, the cases being referred to operation as a last resort. That the general profession still used such methods was not to be wondered at. Surgery, to be successful, must recognise two factors always present in acute intestinal blocks. First, and least important, was the mechanical block in the bowel, the actual obstruction. The second, and incomparably the more severe, was the septic absorption from the distended, congested and perhaps ulcerated bowel above the place of stoppage.

After urging careful preparation of the patient with particular attention to the removal of the stomach contents by means of the stomach tube, he described a method of draining a distended bowel above after the constriction was relieved. In the treatment of gangrenous bowel found in the sac of a femoral hernia, he strongly advocated the use of a supplementary abdominal incision as possessing many advantages when it became necessary to resect the gut. In discussing the post-operative treatment of such cases, he advocated frequent washing of the stomach, the withholding of food by the mouth, and the use of salt solution both under the skin and in the rectum, and he condemned in strong terms drugs in the way of morphine and strychnine.

In cases where an artificial anus had been made, he urged the importance of attention to the passive bowel. He illustrated with the report of two cases how failure to attend to this point in the after-treatment could result in a contracture of the small bowel to such an extent that it would complicate the work of restoring the intestinal continuity.

CYSTS OF THE PANCREAS.

DR. RUFUS B. HALL, of Cincinnati, detailed his further observations on this subject. He reported to the association a case of cyst of the pancreas in 1907, and now reported another case of equal interest which emphasized the great importance of early operation in these cases.

PRESIDENT'S ADDRESS.

DR. W. O. ROBERTS, of Louisville, delivered an address which was literary rather than scientific, and dealt biographically and historically with the names and

achievements of the prominent men who practiced surgery in the South before, during and after the Civil War. It covered the period of years between 1806 and 1892, from the pioneers of the first two decades of the nineteenth century to the few who survived and did work in the last two decades. These names might be divided into two, perhaps three, groups. First, the pioneers; second, the general surgeons; third, the founder of the specialties. In the first are Walter Brashear, Ephraim McDowell, Charles McCreary and Benjamin Winslow Dudley. These the author ranked as pioneers in American surgery. One of whom, Dr. McDowell, was an epoch-making surgeon. The others in early days were conspicuous in the surgery of the South, and did marked and original work, adding much to the medical fame of Kentucky, which was the field of their labors. They were all accomplished physicians as well as able surgeons, and with wonderful industry, learning and art practiced successfully medicine in its three great specialties, as laid down by Hippocrates, namely, medicine, obstetrics and surgery. In those days little beyond minor surgery was done by the country doctor, and the physicians of the larger towns and villages sent their more important cases to the cities, where the men named performed the necessary operations. The specialties of surgery during that period were merely taking form, or being slowly differentiated, and it might be said that these men, while practicing general medicine and doing high-class surgery, did much of the work now done by specialists, and, in short, helped to form and differentiate the specialties. Some of them indeed were its real pioneers. The list being a long one, Dr. Roberts selected a few only for special comment. They were Gunter McGuire, Paul F. Eve, W. T. Briggs, Warren Stone, J. Marion Sims, Samuel D. Gross and David W. Yandell. He gave a detailed biographical sketch of each of these surgeons. The speaker's peroration was reflective, retrospective and eloquent.

### CANCER OF THE UTERUS.

Dr. Reuben Peterson, of Ann Arbor, Mich., described the technic of the radical abdominal operation for uterine cancer, based upon an experience with forty-four cases.

Dr. Willard Bartlett, of St. Louis, Mo., presented an interesting series of lantern slides of distinguished surgeons of Great Britain, of the surgical clinics visited, of the operations performed by these surgeons, as witnessed by the members of the American Clinical Society.

### VOLVULUS OF THE CECUM.

Dr. Horace J. Whitacre, of Cincinnati, reported four cases of volvulus of the cecum, and gave a brief statement as to the nature and frequency of the lesions. In case one, a very movable cecum and ascending colon had passed over in front of them completely around, behind the mesentery of the small intestine, and reappeared in the right side. This patient had suffered three previous similar attacks of obstruction of the bowel which had been relieved by enemata and position. This patient recovered after operation. Cases two and three represented volvulus of the cecum and ascending colon alone, gangrene having occurred in both. One of these patients recovered. A fourth case suffered from volvulus of the cecum and ascending colon, was operated upon in a very few hours, and made a prompt recovery.

Volvulus of the cecum is among the least frequent causes of intestinal obstruction. It had occurred at all ages from sixteen days to eighty years. The symptoms, as a rule, did not differ widely from those of intestinal obstruction from other internal cause. Some authors spoke of a false remission of symptoms after the first two or three days. The mortality was very high even in the cases operated upon (52.2%). The cases reported by the author seemed to present symptoms that were suggestive, namely, first, all suffered premonitory symptoms or previous attacks. Second, all cases presented primary symptoms in the region of the cecum, and a localised distention first appeared at this point. The mortality in this group of cases was 25%.

### PYLOROSPASM.

Dr. Stuart McGuire, of Richmond, Va., said that spasm of the pylorus or pylorospasm was not a disease, but a symptom. It might be caused by rapid eating, by indigestible food, by an ulcer or other lesion of the stomach, but was most frequently the expression of some remote abdominal disease. How appendicitis or cholecystitis caused gastric symptoms had never been satisfactorily explained. It was believed that irritation transmitted to the stomach through the sympathetic nervous system caused an excess secretion of hydrochloric acid. The resulting hyperchlorhydria caused spasm of the pylorus; the pylorospasm caused retention of food beyond the physiological limit, and finally there came motor insufficiency, food stagnation and dilatation of the stomach. The most prominent symptom of pylorospasm was a cramping pain in the epigastrium, which might last only a few minutes or might continue for several hours. In some cases the spasm might relax suddenly; in others it might terminate slowly and gradually. Some patients had attacks several times a day, others at intervals of weeks, and others still only once or twice a year. In the interval between attacks the digestion may be normal. During attacks peristalsis of the stomach was increased, but food could not pass through the pylorus, and often relief came only after vomiting. The patient usually dieted strictly, and lost flesh and strength steadily from starvation and auto-intoxication. In no other class of patients, with possibly the exception of epileptics, was it necessary to be so thorough in preliminary examination and so patient in post-operative treatment. The real cause of the condition must be found, and after it had been removed the patient must be systematically treated until the hypersensitiveness of the pyloric muscle was relieved, and its spasm habit overcome.

After reporting an interesting case, Dr. McGuire emphasized the following points: (1) The necessity of differentiating between gastric symptoms due to organic disease of the stomach and those reflex from other organs. (2) The impropriety of doing a gastro-enterostomy for spasm of the pylorus. (3) The advisability at the time of operation of examining all abdominal organs and correcting every abnormality, lest the obvious might not be the real cause of the symptoms. (4) The importance of the post-operative and post-hospital treatment of patients to overcome the spasm habit of the pyloric sphincter.

### TUMORS OF THE JAW.

Dr. Willis F. Westmoreland, of Atlanta, Ga., presented the pictures of a type of tumor that so far as his clinical experience went had practically disappeared. He had not seen one in years. This type of tumor seemed to have occurred almost exclusively in the negro. In 38 cases operated upon by his father, only one was white. In the 5 cases occurring under his observation, all were in the negro. Among us these cases were known as fibro-cystic tumor; this title very closely described the gross clinical appearance of the tumor. In reviewing the literature of this subject Dr. Westmoreland said: "I am not able to place it, though

it seems to conform more closely to the species of follicular odontoma of the genus odontomata in Bland-Sutton's classification. I would class it as an anomalous form of this species. I should judge they belong to the follicular rather than the epithelial odontoma, although they have never shown malignancy, while the epithelial type occasionally did." Clinically the tumors presented a uniformly well-rounded mass, the surface of which felt hard and dense to the touch. Firm pressure upon the tumor with the fingers would always at some point elicit a distinct crackle; that was characteristic, as in a way diagnostic, though not differentially so, as it occurred in other species of odontoma.

In a research of the literature of tumors of the jaw, which up to a few years ago were classified under the generic term of dentigerous cysts, the essayists had probably had the same trouble as he had, seeing them in their later development and being unable to properly classify them. But in the negro one fact seemed to be true, and that was, no matter what the original type, the later development was always along the same line.

### TRANSFUSION IN PELLAGRA.

DR. H. P. COLE, of Mobile, Ala., presented a review of 20 cases of this disease, and then drew the following conclusions: In the transfusion of 20 cases of pellagra they had found no ill effect resulting directly from the operation. They might safely resort to transfusion in the severe type of case steadily retrogressing, under approved therapeutic procedures. They had noted no advantage in the employment of a donor who had recovered from pellagra, as compared with the donor who had never had pellagra. There was apparently no advantage in the use of a relative for a donor as compared to the use of a non-relative. The recoveries following transfusion in the grave type of cases (60%) compared most favorably with the recoveries (10% to 20%) in the same type of cases in which other therapeutic measures were employed. The employment of transfusion in the terminal stages of pellagra must be undertaken with a full knowledge of the difficulties and dangers of the operation. Without careful selection of the cases and unprejudiced conclusions, this procedure would fall into an undeserved ill-repute.

### THE CAUSAL RELATIONSHIP BETWEEN INJURY AND CANCER.

DR. WILLIAM B. COLEY, of New York, stated that in a previous paper [1] he published an analysis of 170 cases of sarcoma that had come under his personal observation, and stated that no clinical feature of the disease had impressed him more strongly than the frequent association of trauma with its early manifestations. In 46 of these 170 cases there was a definite history of antecedent trauma. Since this paper was written he had observed 740 additional cases of sarcoma, making a total of 910 cases. In 236 cases (26%) there was a definite history of antecedent trauma. The interval elapsing between the injury and the development of the trauma was less than two weeks in 63 cases (27%); less than a month in 97 cases (42%); tumor occurred within the first six months in 137 cases (60%). The disease originated in the bone in all cases (47%) and in the soft parts in 125 (53%). In making a study of all his cases of carcinoma, he presented an analysis of 125 cases of carcinoma of the breast. In these there was a definite history of previous injury in 52 cases, or 41%. In 5 of these the tumor was noted within a week after the injury; in 12 cases within the first few weeks; in 19 within the first month, and in 36 within the first 6 months. He further presented 3 cases that had come under his personal observation which fulfilled the strict, scientific test which Segone required, namely, that a medical examination had been made of the parts by a competent surgeon prior to the accident. He did not attempt to offer a complete explanation of the influence of injury upon the development of malignant tumors, but said that he personally believed more strongly with increasing experience that all types of malignant tumors were of extrinsic origin or parasitic.

[1] Ann. Surg., March, 1898.

The following papers were also read: "Hydatid Cyst of the Liver, Successfully Treated by Operation," by Dr. John C. Oliver, Cincinnati; "Diagnosis of Extra-uterine Pregnancy," by Dr. E. Gustav Zinke, Cincinnati; "Omenopexy," by Dr. Maurice H. Richardson, Boston; "Tumors of the Breast," by Dr. William C. McCarty, Rochester, Minn.; "Causal Relationship between Injury and Cancer," by Dr. W. B. Coley, New York; "Hypernephroma Arising in the Right Testicle," by Dr. James E. Thompson, Galveston, Tex.; "Degeneracy, the Underlying Cause of Disease; How the Unfit Perish," by Dr. Chas. P. Noble, Philadelphia, Pa.

### OFFICERS.

The following officers were elected for the ensuing year: President, Dr. Rudolph Matas, New Orleans; First Vice-President, Dr. Guy Leroy Hunner, Baltimore; Second Vice-President, Dr. J. Garland Sherrill, Louisville; Secretary, Dr. William D. Haggard, Nashville; Treasurer, Dr. William S. Goldsmith, Atlanta.

Washington, D. C., was selected as the place for holding the next meeting; time, December, 1911.

## Book Review.

*Obstetrical Nursing for Nurses and Students.* By HENRY ENOS TULEY, A.B., M.D., Professor of Obstetrics, Medical Department of the University of Louisville. Seventy-three illustrations. Louisville, Ky.: John P. Morton & Co., Inc. 1910.

This little handbook on obstetrical nursing will prove very satisfactory to many nurses. It is most elementary and the style is very clear and concise. The illustrations are on the whole not satisfactory. They often do not show the points which the author wishes to make clear. The one on holding the fundus after labor is poor and no nurse could hold a fundus satisfactorily that way. In making up saline solution, the author does not speak of filtering the solution. When he is speaking of post-partum hemorrhage he gives the nurse no hint that an internal concealed hemorrhage may take place. His paragraphs on the treatment of premature children are too superficial and no nurse could obtain from them sufficient advice to care properly for such children. His description of the use of the Bier bell in mastitis is absolutely wrong, and finally the reviewer regrets that he has devoted two full pages to Schultze's abominable method of artificial respiration. With these many criticism sit, however, is an excellent book and we only hope that in future editions some of these mistakes at least will be overcome.

THE BOSTON

# Medical and Surgical Journal.

THURSDAY, MARCH 2, 1911

*A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.*

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; $6.50 per year for all foreign countries belonging to the Postal Union.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 809 Paddock Building, 101 Tremont Street, Boston.*

*All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.*

*Remittance should be made by money order, draft or registered letter payable to*

W. M. LEONARD,
101 Tremont Street, Boston, Mass.

## NOTING THE "IMPERCEPTIBLE."

Francis Galton gave prodigiously to science, far more than most of his contemporaries, howsoever generous they were; and perhaps his most valuable contribution was the example of his habit of careful observation. He scrutinised a great deal that most men did not even see. In the realm of art this is rightly esteemed the essence of genius — to have vision of, and to depict, "things invisible to mortal sight"; and in science also is this discernment of things unappreciated by the average man a faculty of genius. Such discernment was temperamental in Galton, and he carried it into the minutiæ of his life. For example, he went some months before his death to the house of a neighbor where a paper of his own was to be read before a little company. Too deaf to hear anything, he nevertheless watched the bearing of the audience. "My experience is that when ladies are not interested they indulge in fidgits; and the average of their fidgits is about two per minute. Now, the average of the fidgits of the ladies present did not exceed two per five minutes; this [he humorously noted] proves to me that they have not been bored, and is as much as I could hope for." On another occasion Galton sat for his portrait; to relieve the tedium his active mind sought something of interest. He counted the strokes of the artist's brush, which numbered about twenty thousand; and upon this experience he based a paper in *Nature*, in which he stated: "Græf described the very last stage of his portrait as 'painting the buttons.' When this stage was reached, he poised his brush for a moment, made three rapid twists with it, and three well-painted buttons were thereby created. The rule of three seemed to show that if so much could be done with three strokes, what an enormous amount of work must go to the painting of a portrait which required twenty thousand of them. At the same time, it made me wonder whether painters had mastered the art of getting the maximum result from their labor."

These slight incidents indicate, nevertheless, the important capacity for attending to the unconsidered; it is by such capacity that seemingly inconsequential facts have been elicited, upon which many wise deductions of science have been based. It was by the same kind of mental gift that Darwin, Galton's cousin, evolved his epochal discoveries and fostered their acceptance. The material — the earthworm, the climbing plant, myriad phenomena — lay before every eye, but nobody else than Darwin had troubled himself to notice them. Genius has been defined as an infinite capacity for taking pains; if to this be added alertness in perception, and interpretation of facts perceived, one has, for science at any rate, a fairly adequate definition of genius.

This faculty of fixing the attention upon the unnoticed things that are under everybody else's noses is the chief essential to scientific discovery. It is recorded that Ricardo's advances in political economy were by reason of his skill in taking account of the "imperceptibles." Of course, this is not all; one must add to the seeing eye the understanding mind. Agassis was wont to take his students out to a great bowlder near Cambridge and ask what they saw on it. Most saw nothing; some saw vague scratches, but only the master had discerned in these scratches ice-markings — proof that the bowlder had been deposited where it was by a glacier.

Oftentimes this power of observation cannot be acquired; it is a precious gift of nature. Nevertheless, something can be done to develop in those not thus gifted a faculty for examining and getting the truth out of generally unconsidered "trifles," and herein lies in large part the usefulness of research work and laboratory methods in our colleges and universities. It is by what Professor Osborn has termed the "centrifugal" method in education that the student is induced to scrutinise, to investigate for himself, to awaken the latent powers of his own mind. And it is to such original and inventive intellect that the world owes most of its stupendous medical and surgical progress during the last six decades.

But not only in abstract science is this subtle gift of value; it is most important in the success-

ful diagnostician. Such an one must first of all have the selective instinct. He must, to begin with, make an exhaustive anamnesis, eliciting every fact, howsoever trivial it may seem, in the case before him, else no reasonably safe deduction is possible. This done, the whole history of the patient must be surveyed. A diagnosis is then reached from a judgment of many factors, one among which might be irrelevant, several of which taken together would be suggestive, a number of which combined would be conclusive.

## PROPOSED HOMEOPATHIC SANATORIA FOR CONSUMPTIVES.

IN another column we publish a communication relative to our editorial under the above title in the issue of the JOURNAL for Feb. 16. Some of our correspondent's comments are well founded, but his statements also contain some errors which it seems just to point out.

In the first place, he declares that the "statement that in the sanatorium at Rutland, containing 350 beds, there are two services of equal size, is not and *never has been* correct." As a matter of fact, from the very beginning there were at Rutland two services, one regular, one homeopathic, to which patients were at first assigned alternately. As the institution increased in size, and more assistant physicians were appointed, the services became more and more uneven, and five years ago three services were established, two regular, one homeopathic. There are, at present, on the homeopathic service at Rutland, 116 patients.

In the second place, our correspondent takes exception to the statement that "no patient at this institution has ever made a request for homeopathic treatment." It is true that no such request has been made since the institution has been in charge of the present board of trustees. Moreover, the stenographic report of the hearing, to which our correspondent later refers, contains the statement by Dr. Cabot, chairman of the board of trustees of the Massachusetts Hospitals for Consumptives: "As a matter of fact, there has been no demand for homeopathic treatment in any of the other three sanatoria, at least so my superintendents tell me. Of course, I cannot say that some of the underlings in the sanatoria have not been asked, but there has been no real demand, or we should have considered the question of looking after it."

In the third place, our correspondent objects to the statements that the treatment given on the two services is identical and that drugs play little part in the therapeutics of tuberculosis. In spite of what he affirms, however, we still maintain that in the treatment of phthisis drugs play a very incidental part. They may be desirable as palliatives, or in the treatment of intercurrent symptoms or disturbances, and as such would be employed by any intelligent physician, but they are not directly concerned with the cure of the disease. Differences in the detail of their administration might exist, but the treatment given on the two services, so far as tuberculosis is concerned, would remain essentially identical.

Finally, our correspondent says: "Did you know that the number of *regular* private sanatoria in our state is almost as small, and that the homeopathic one you refer to treats almost as many patients, as all the rest put together? *That is so.*" As a matter of fact, there are approximately 75 patients at the homeopathic sanatorium in question, and in the regular private sanatoria in this state, approximately 600.

It is true that we unintentionally overstated the present demands of the homeopaths, owing to ambiguity of the bill in which the first and second resolves are not stated as alternatives. The petition to the legislature accompanying the bill, we were not given an opportunity to read. At the hearing on this bill on Feb. 27, it was distinctly stated by the petitioners that their request is for only one sanatorium of 150 beds, either a new institution or the existing one at North Reading, and that on their obtainment of either, they will withdraw from their present opportunity and privilege at Rutland. Their preference is for an entire independent institution rather than for a representative share in those now existing or hereafter to be established.

We regret if our former editorial seemed in any way to misrepresent the case of the homeopaths. If it did so, such misrepresentation was entirely inadvertent, and we believe that no intrinsic injustice has been done.

## REPORT OF THE RHODE ISLAND TUBERCULOSIS COMMISSION.

PRESUMABLY the fundamental problem of tuberculosis is the same in all communities. In different localities, however, the problem may present itself under different aspects, on account of varying local conditions and the personal equation of various observers; and one community may, therefore, reasonably hope and desire

to learn from the experience of another. In view of the recent work of the Massachusetts Tuberculosis Commission, on which we made editorial comment in the issue of the JOURNAL for Dec. 8, 1910, there is particular pertinence and interest in the report of the Commission on Hospitals for Advanced Cases of Tuberculosis made to the General Assembly of Rhode Island in January last.

The Rhode Island Commission was appointed in February, 1910, "to investigate as to the need of hospitals for persons afflicted with tuberculosis in its advanced stage, and to report thereon with a comprehensive plan for the care of such cases." Like the Massachusetts Commission, it made an extensive study of the prevailing conditions with regard to the disease, and presents its results in tables of data, with comment and discussion. The most important of its conclusions and recommendations are:

1. That the logical measure for the prevention of tuberculosis is segregation, especially of advanced cases.

2. That the care of tuberculous patients unable to be properly cared for at home should be undertaken conjointly by the state and its municipalities, and that the state should subsidize local institutions to the sum of six dollars a week for each non-paying patient.

3. That provision should be made for proper instruction about tuberculosis to all consumptives and their families, and to children in the public schools.

It is interesting to note that the commission estimates that the thousand deaths from tuberculosis in Rhode Island each year represent a total annual economic loss to the community of over $8,373,750; whereas, in New York, Prof. Walter F. Wilcox, of Cornell University, places the annual economic loss from some 16,700 deaths of tuberculosis in that state at $64,000,000.

In its recommendation of segregation and state subsidy, the opinion of the Rhode Island Commission coincides with the views of the Massachusetts Commission, and in so far is an endorsement and argument in favor of the policy advocated by the latter.

## A NEW BACTERIOLOGIC MUSEUM.

IT is announced, in the issue of *Science* for Feb. 24, that there has been recently equipped at the American Museum of Natural History "a laboratory to serve as a central bureau for the preservation and distribution of bacterial cultures of both pathogenic and non-pathogenic organisms, and particularly of types of new forms and varieties." The possible educational and scientific value of such a bacterial museum and distributing station are obvious. For its completeness it must depend to a considerable extent on the contribution of specimens from other laboratories and from individual bacteriologists. "It is hoped," continues the announcement, "that the laboratories of medical schools, colleges, boards of health, agricultural experiment stations and those engaged in biochemical work of all sorts, will furnish the museum with cultures at present in their possession, and the laboratory is now ready to receive and care for such cultures. Only organisms which have been identified and which have a definite history are desired as a rule; but in the case of rare species, like the organisms of certain tropical diseases, this rule may be departed from. . . . The laboratory plans also to keep on file descriptions of bacterial species in print or arranged in the form of the standard card and will be grateful for copies of any such descriptions. Descriptions filed in the department will be carefully preserved and living cultures will be kept in good condition, so far as possible, and will be supplied at all times without charge to corresponding laboratories and furnished, so far as possible, and with a reasonable charge, to schools and other institutions which may desire them. . . . Pathogenic forms will be sent only to properly qualified persons."

Such a laboratory should be of great service to teachers of bacteriology, and it is to be hoped that all institutions and persons to whom this request for contributions is addressed will make prompt response and will co-operate in future to maintain the successful efficiency of this new scientific undertaking.

## POTENTIAL LONGEVITY IN MAN AND OTHER ANIMALS.

IT is reported from London that in a recent lecture before the Royal Institution on "Problems of Animals in Captivity," Dr. Chalmers Mitchell, secretary of the London Zoölogical Society, said that "it is extremely doubtful if a really natural death ever does occur in any kind of animal, including man." All deaths from trauma, infection or neoplasm are to be regarded academically as accidental. Any animal living in perfectly hygienic surroundings and guarded from all such accidents must necessarily die a natural death by going to pieces all at once,

like the "one-hoss shay." Even under these utopian conditions, however, Dr. Mitchell places the maximum potential age of only six animal species at over one hundred years, namely, elephants, whales, man, eagles, parrots and turtles. It is somewhat comforting to reflect that we are in such excellent and select company in this potentiality of centenarianism, and that our near kindred, the monkeys, are excluded therefrom. Recent serologic and pathologic experiments, as well as many social observations, have seemed to bear out the statement that

> "We are very little changed
> From the semi-apes who ranged
> India's prehistoric clay";

and it is encouraging that in respect of potential longevity, at least, we have improved on our arboreal predecessors.

## INSANITY IN LONDON.

WE have of late become quite accustomed and even resigned to the gloomy belief that insanity, like cancer and pneumonia and cardio-renal disease, is increasing steadily in all civilised communities, and at a rate proportionately faster than that of the total population. It is, therefore, particularly comforting to learn, from the recently issued twenty-first annual report of the Asylums Committee of the London County Council, that during the year ended March 31, 1910, the increase in the number of insane patients under treatment in the public institutions of the city was only one hundred and ninety-eight, the smallest annual increase recorded since 1892. Moreover, as in our own country and state, the incidence of insanity is proportionately greater among immigrant aliens than among native inhabitants. Perhaps such facts may justify the consoling conclusion that, after all, civilization is not necessarily self-destructive, and that in time education and adaptation may enable the fittest of us to survive even the menace of mental degeneracy, race suicide and other kindred evils.

## MEDICAL NOTES.

SMALLPOX AT LACHINE. — Report from Montreal, Canada, states that a single case of smallpox and three of chicken-pox have recently occurred at the convent of St. Anne, in the neighboring suburb of Lachine. Street quarantine has been established.

THE UNIVERSITY OF PENNSYLVANIA MEDICAL BULLETIN. — We are informed that the *University of Pennsylvania Medical Bulletin* begs leave to state that the magazine was discontinued on March 1, 1911.

CHOLERA IN HONOLULU. — Report from Honolulu states that on Feb. 24 two cases of Asiatic cholera, both in native Hawaians, were discovered in that city. One of the patients died the next day. The Territorial Board of Health has established rigid quarantine, and it is hoped that by these precautionary measures further spread of the infection may be prevented.

DIPHTHERIA AT BALTIMORE. — Report from Baltimore, Md., states that there has been an outbreak of diphtheria at the Johns Hopkins Hospital in that city. On Feb. 25, there were said to be 39 cases in the hospital, of whom 12 were medical students, 10 nurses, 2 graduate physicians, 1 employee and 14 ward patients; on Feb. 26, the appearance of 4 more cases was reported; the last report gives 75 cases. The entire hospital has been quarantined and the Johns Hopkins Medical School has been ordered closed until further notice.

APPOINTMENT OF MEDICAL SUPERINTENDENT, JOHNS HOPKINS HOSPITAL. — Dr. Winford H. Smith has resigned as medical superintendent of Bellevue and Allied Hospitals, an office he has held for the past two years, to accept the same position at the Johns Hopkins Hospital, Baltimore. At the latter he succeeds Dr. H. M. Hurd, who has been connected with the hospital for some twenty-five years and who will still remain a member of its medical board. Dr. Smith was graduated from Johns Hopkins University in 1903, and from 1906 to 1909 was medical superintendent of the Hartford General Hospital.
